THE PHOENIX TROUBLES.—The *Tampe News* announces the resignation of Supt. Alex. Trippel, of the Phoenix mine, for the very good reason that the ore, in quantity, averages only \$2 per ton in gold. Dr. Trippel was called to the management after the plans of development and improvement had all been arranged and partially executed, and the costly mill of 100 stamps was in course of erection. This heavy expenditure was ill-advised and the site for the mill badly chosen, entailing an expense, as we are informed of one-third more in delivering the ore to the mill than would have been necessary had the mill been more favorably located. Dr. Trippel is in no way responsible for the present difficulties. We are also told that the company is in litigation with Fraser & Chalmers, of Chicago, over the payments on the mill, and it looks very much as though another disastrous failure is about to be recorded in the attempt to make the Phoenix a paying enterprise.

Two wealthy companies had "gone broke" on the property previous to its purchase by the present owners, and it had become notorious in mining circles, and columns in the mining papers were given to contentions as to its value and the practicability of transforming it into a paying property.

NEW GOLD CAMP.—*Mohave Miner*: Col. Harley Fay, who has just returned from the new gold camp on Burro creek, gave a *Miner* reporter the following facts about that section:

The claim owned by McGee, Eshom and Josephi has a shaft down 40 feet in good ore. There is about 20 tons of ore on the dump that will run about \$100 per ton. The ledge is about 12 inches in width and is the best showing in mine. Jeff Bland has a good showing in his mine a short distance from the above-mentioned claim. The ore shows the full length of the claim and partly across the claim adjoining, owned by Charley Wilson. Frank Cofer has a claim named the Red Bird that shows well on the surface and has some other valuable showings. W. A. Neal, Al Boner and many other prominent Sandy ranchers have claims in the new camp. Parties who contemplate going to the new camp should lay in a supply of grub, as there is no store there yet and the nearest supply point is Signal, 25 miles distant. The camp is well situated for economical work, being only two miles from Burro creek, where an abundance of water can be obtained for milling purposes. Enough wood can be obtained in the vicinity to run a small mill for two years.

BEGIN WORK.—*Mohave County Miner*: Halley & Lynch have commenced work on their sampling works. The frame work is already up and everything will be ready for the machinery next week.

It is rumored that W. H. Lake, through Ewing & Helmrod, will soon start a branch sampling works at White Hills for the purpose of handling the ores of that camp. Competition makes business lively. This will be a great accommodation to the miners of White Hills who have small lots of ore to sell.

BRITISH COLUMBIA.

BIO VEIN OF COAL.—A Victoria dispatch says: A valuable seam of coal has been discovered three miles back of Sumas lake, and a syndicate of Scottish capitalists has been given an option on surrounding property. It is well known that some time ago coal indications were found in the vicinity, and a number of Vancouver men, ex-Mayor Oppenheimer and J. Bellamy among them, sent an expert to inspect the ground.

The vein was traced down the side of the mountain, and on the expert's advice some sinking was done which is said to have resulted in disclosing a fine vein 37 feet thick. Negotiations were begun in November with the Scotch syndicate, who was to send experts, and if the find proved as valuable as supposed, they expressed a willingness to spend \$1,000,000 developing the property.

What is considered the most valuable part of the find is in the Indian reserve, close to the mountain. A diamond drill is to be used in

thoroughly prospecting the ground immediately.

IDAHO.

SNAKE RIVER PLACES.—*Boise Democrat*: Rev. McReynolds and Messrs. Cook, J. B. Foster and Schneider took a flying trip lately to the Martin-Schneider claims on Snake river. The claims are about ten miles above Walters' ferry. They have a high bar of about 120 acres, on which a number of men are rocking and taking out about \$2.50 a day to the man. They wheel the gravel about 60 yards, to get it to the water. Messrs. Martin and Schneider are figuring on a pump to raise the water 40 feet from the surface of Snake river to the top of the bar, and if successful they will have a good thing. The gold on these claims is not the ordinary float or scale gold of Snake river. It is fine, but is rough floor gold, and when seen through a glass has a rough jagged appearance, showing that it has not traveled far. It is very easily saved in a rocker or sluice boxes. Immediately at this point on the river is a large cliff of cement some three feet thick and extending four miles up the river, all of which contains some gold, and there is no doubt that the gold on this bar comes out of this body of cement, and should the cement prove to be rich enough to pay for working, the day of gold mining on Snake river is just beginning to dawn.

MONTANA.

WORK AT BUTTE.—*Inter-Mountain*, Feb. 24: The Montana Ore-Purchasing Company is now employing about 350 men. In addition to the supply of ore treated at this company's smelter from the Ramus and Gulgarry mines, a large quantity of ore from other properties, notably the Eveline, is also being worked there. The Eveline is shipping very rich ore.

The Clark syndicate deal seems to be in statu quo. During this week an effort was made to secure a hold on the McQueen addition, across Silver Bow creek from the Heuze smelter, but the owners would not give it. They want to sell outright. It was presumed this ground was wanted for the purpose of building a smelter by the proposed Clark syndicate, but this was only conjecture. The site was considered a good one, water being available. Connection by rail could also be made with the Montana Union to tap the mine of the proposed company.

Miles Finley and T. R. Hinds, according to authentic reports, have struck a fortune in the Buffalo. This is an Anasocua property, west of the Mountain Con. holet, and the lessees have a three-year lease. It is claimed that they have opened up a body of ore that contains 60 per cent copper and is three sets wide. It is also said they have \$25,000 worth of ore on the dump. Arrangements are now being made to build a spur of the B. A. P. road to tap the Buffalo.

Butte is now giving evidence of becoming an important lead-producer. Heretofore lead ore has been passed by as worthless, but recent developments show that there is plenty of lead here in paying quantities. The Humboldt, Gray Rock, Josephine, Banker and Magna Charter mines are now making regular shipments of lead ore, the Humboldt, located in Centerville, being the principal producer. The lead ore runs in chutes of large proportions. Some are carrying 50 per cent lead has been taken out. Lead ore finds a ready market.

OREGON.

THE SANTIAM GOLD DEAL.—The *Salem Statesman* has the following: A mining deal was consummated in Albany Saturday which means a great deal for this part of Oregon. Under it the Albany Mining and Milling Company banded all their property in the Santiam mines to Thomas G. Drew and C. C. Clark, two wealthy mine owners recently in the mines, for \$40,000. Mr. Drew, one of the present owners, is the principal owner in the famous Hammerley mine at Jumpoff Joe, and is a practical mining man. When questioned as to his new property, he said: "Mr. Clark and I went in to look over the property about three weeks ago, and were so well satisfied with what we saw that we closed the deal immediately upon our return on Saturday. The mineral belt in which the property is situated is the finest I have seen, and I may say that my travels have not been confined to Oregon alone. The ore is low grade, assaying from \$8 to \$28 per ton, but there is plenty of it and it can be easily taken out. Over 3500 feet of tunneling, in the shape of development work, has been done, and the body of ore exposed to view is sufficient to keep a 10-stamp mill in constant operation for ten years. The vein is from four to eight feet wide and contains pay rock from wall to wall.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

A New System of Pumping.

Wm. Nance, of Grass Valley, Cal., is the patentee of a new system of pumping, by which it is claimed the weight of the required machinery is reduced one-half, and the necessity of heavy balance rods in the shaft is dispensed with. In many essential points it is asserted that superiority is manifest, notably in the automatic tightening and lubricating of the stuffing-box gland when working under water.

Newly Established.

E. A. Rix, formerly of Rix & Birrell, is newly established, and is in business for himself at 104 First street, San Francisco. He is agent for standard makes of mining machinery and supplies, engines, boilers, etc.

Market Reports.

The Markets.

SAN FRANCISCO, March 8, 1894.

The past week has presented no encouraging features in the silver market. Stocks continue large, and it is reported in London that £1,000,000 in bullion is about to be placed on the market. The quotations to-day were 27 1/2 d in London, 59 1/2 c in New York. There has been no change during the week in copper and lead.

New York Prices.

NEW YORK, March 8.—Following are the closing prices for the week:

Mining Share Market.

SAN FRANCISCO, March 8, 1894.

Mining Cash Balances.

Following is a statement of the cash balances of certain mining companies on the first Monday of March, as required by law:

Alpha	\$10,783	Justice	\$8
Alta	7,879	Kentuck	4,200
Belcher	1,028	Lady Washington	464
Best & Belcher	11,578	Mono	3,853
Bullion	13,137	Mexican	19,041
Bodie	4,986	Nevada	1,684
Caledonia	7,945	Nevada Queen	1,771
Challenge	853	Ophir	15,962
Chollar	7,177	Overman	4,471
Con. Imperial	571	Potosi	1,418
Confidence	6,200	Savage	5,254
Con. New York	8,118	Scorpion	2,147
Con. Cal.	1,401	Seg. Belcher	289
Crown Point	10,958	Sitter Hill	515
Exchequer	2,858	Sierra Nevada	23,776
Gould & Curry	791	Standard Con.	83,664
Hale & Norcross	18,070	Union Con.	10,775
Julia	1,683	Utah	2,005

The indebtedness of other companies on the 5th is reported as follows:

Andes	\$107	Grand Prize	\$238
Buller	2,867	Occidental	\$9,000
Commonwealth	21,739		

As an offset Occidental Consolidated has \$1534 in the treasury. Justice is collecting an assessment. California is near the assessment line.

The levying of several assessments caused a weaker range of prices in the Comstock market during the week. These assessments, and others which are to come, have been in a measure discounted among stock dealers. During the past two days, however, there has been some improvement, Ophir and Mexican and the shares of the other mines at the north end of the Comstock continued to be strong features in the market to-day. Most of them

opened at an advance on yesterday's closing prices and were well sustained up to noon. Con. California and Virginia and the other stocks showed no particular change during the forenoon, yet their prices did not go down. Judging from the very large number of people, including some who were lately high bulls on the stock, who by their talk show that they would like to have Con. California and Virginia decline to \$3 and under, quite a high short interest in it has accumulated.

A drop in Con. Cal. & Va. Monday was attributed to disappointment among certain holders because Superintendent Lyman's official report of last week's work in the mine did not confirm the stories about six feet of \$50 ore having been struck in the upraise from the Rule drift on the 1000-foot level.

Coast Industrial Notes.

—Santa Clara will vote on the 13th of March on a proposition to refund the city's indebtedness.

—The Santa Clara Bank has entered suit against its debtors. Money is needed to square accounts with creditors.

—San Diego will soon be joined to La Mesa by a motor line. Work will be commenced at once, and in 30 days it is thought the line will be in operation.

—The bank at Horre, Mont., has closed its doors because of its inability to negotiate its papers. Its assets are \$14,000 while the liabilities are placed at \$9000.

—The Odd Fellows' Lodge of Ontario, Cal., has let contracts for a building and hall. The building complete, with hall furnishings, will cost about \$5000.

—To facilitate work on the ditch of the Consolidated Canal Company at Mesa, A. T., a steam shovel has been secured. An electric-light plant has been obtained, and work will be carried on night and day.

—Judge Fullerton has ordered the sale of the Oregon Pacific Railroad at a date no later than June 1st, the date to be fixed by the sheriff. Bidders will be required to make a deposit of \$200,000.

—The Peoria canal at Gila Bend, A. T., is 40 miles long and covers 50,000 acres. The dam is being completed as rapidly as possible, 160 men being employed in its construction. When finished it will be 1920 feet long, 17 feet high and 32 feet wide.

—It is definitely stated that work will be resumed on Humboldt bar April 1st. This means the resumption of work at the quarries, in the woods and at the mills. The resumption of work will give employment to a large force of men.

—An Ottawa dispatch to the Victoria Colonist says that the Government has entered into a ten-years contract with James Huddar, subject to the sanction of Parliament, for a line of Canadian Atlantic steamers, capable of steaming 20 knots an hour, to connect with Australian steamers by the Canadian Pacific railway. Quebec and

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs in the shaft. Works with 10 per cent less power. First outlay one-third less. Suitable to any underly or downright shaft. Occupies less space in the shaft. Has been tested a year and proved to work satisfactory in every respect. GLAND OF STUFFING-BOX TIGHTENED AND LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING OR BUCKET PUMP.

The valve-clack and bucket can be changed when the pump is under water. Bucket lasts six times as long as a leather geared bucket, often saving expense of putting down another pump, especially in jack-head pumps, where the bucket and clack cannot be changed under water. Special attention is called to this new system of pumping, and also to the self-screwing stuffing-box and new bucket gearing, which are applicable to all kinds of plunger, force, and bucket pumps.

WM. NANCE, Grass Valley, Nevada County, Cal.

Hallfax are to be the Atlantic terminals. It is expected that the Imperial Government will handsomely subsidize the service.

—A Chicago company is figuring on buying Santa Rosa's water works, but insists that a quarter of the stock should be taken in Santa Rosa. This is to quiet the feeling of opposition that has developed among the people. It is proposed, if a proper understanding can be reached, to put \$500,000 into the enterprise.

—Otto von Geldern, the well-known civil engineer, has been retained by the directors of Modesto Irrigation District to make surveys and estimates for the completion of the flumes and canal of the Modesto district. There remain about 4000 feet of flume to be constructed and a small portion of the work in the canal to survey.

List of D. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

RULER.—Ferdinand Frank. No. 515,522. Dated Feb. 27, 1894. This invention relates to an improved construction for desk rulers, the object of which is to provide a combined and flexible ruler, the rigid portion of which is adapted to serve as a guide for drawing straight lines upon flat surfaces, while the flexible portion fits itself to the curved

pages of a ledger or other book, so that straight lines may be drawn with its edge as a guide, the rigid portion of the ruler serving to steady the curved part.

DEVICE FOR DRAWING STEAM BEER.—Constant Harth, S. F. No. 515,470. Dated Feb. 27, 1894. This invention consists of the interposition of a chamber or receiver between the cask and the drawing-off faucet, whereby beer can be drawn from fresh casks in a comparatively solid condition with but little or no escape of gas, and the gas which does pass into the chamber will immediately pass back into the cask as soon as the drawing-off cock is closed.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine, by the hydraulic process from Thomas Alderson in the Spanish Hill Gravel Mine, near Placerville, El Dorado Co., to deposit tailings behind a dam on the bank of Cedar Creek; from the El Dorado Water & Deep Gravel Mining Co. in the Spanish Hill Hydraulic Mine, near Placerville, to deposit tailings behind brush dams in Spanish Ravine; from Pascoe & Gruben in the Eureka Hydraulic Mine, near Placerville, to deposit tailings behind a brush dam on Cedar Creek; from John Blair et al. in the Mitchell Hydraulic Mine, near Placerville, to deposit tailings behind brush dams in Spanish Ravine; from James Hackett in the Oriental & Tahoe Mine, near Rough & Ready, Nevada Co., to deposit tailings behind dams on the side hill and in a ravine; from E. B. Jacks in the Badger Hill Placer Mine, near Spanish Ranch, Plumas Co., to deposit tailings behind a rock dam in Spanish Creek; and from Tucker & Brown in the Grub Flat Placer Mine, near Spanish Ranch, to deposit tailings in an old hydraulic pit. Notice that a meeting will be held at Room No. 32 Flood Building, San Francisco, Cal., March 27th, 1894, at 1:30 P. M.

Manufacturing Pipe from Steel and Iron for Mining.

Schwab, Ingram, Batchelor & Co., Hardware Merchants of Sacramento City, have recently erected in that city a building 42x100 feet, for the manufacturing of sheet steel and iron pipe, for mining, water works, power and irrigating purposes. We are now informed that they have just completed another building 34x70 feet, which is used as a dipping house. After the pipe is manufactured it is sent to the dipping house, where it is submerged in a hot bath of a solution of double refined Asphaltum and Maltha, which renders the pipe almost indestructible. The pipe is then placed on a platform 64x74 feet, alongside the railroad track, where it is loaded on cars. This is done without chafing or the abrasion of the coating, which always occurs when newly dipped pipe is hauled on wagons to the railroad. This firm, being equipped with the most modern factory and appliances, are manufacturing the best pipe on the coast, not only in the quality of the material used, but the general workmanship and finish is unexcelled.

MANUFACTURERS FOR THIRTY-THREE YEARS.

CALIFORNIA WIRE WORKS

OFFICE, 509-511 MARKET ST., SAN FRANCISCO, CAL.

LOS ANGELES AGENCY, LOS ANGELES, CAL.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED }
{ Sept. 19, 1893. }

CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.

{ FRANK BARRERE, }
{ Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE PACIFIC BRANCH UNION IRON WORKS, 127 FIRST STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

— SAVED —

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.
SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILE IN OPERATION.
CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE (at present).....\$350 EACH,
Including Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ore. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,

E. L. BALLOU, Propr. Ballou Reduction Works.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

The Habit of Exaggeration.

It ought to be well understood by all who know anything of the history of mining that exaggeration in the long run does serious damage to the permanent interests of a mining district. It is also a well-known fact that many districts have been built up by assays and let down by working results. There always has been too much flamboyant nonsense about mining discoveries, though it is gratifying to realize that in a measure it is growing beautifully less each year, and truth now may, and again may not, be seen through a mass of figures and dollar marks. It may be added also that a great deal—the largest part—of this general distortion of facts is unconscious and put forth with no intent to deceive; but, for all that, it is exaggeration, and the tendency of the intelligent pub-

lic, at most, not too broad and conspicuous, and should not appear as the sole motive of the review. Capital is generally able to draw its own conclusions, when placed in possession of the facts. It has a habit of weighing statements as a judge weighs testimony, and estimating probabilities at their true value. Capital is cautious because it has a right to be cautious. Naturally it wants to eliminate, in any given venture, the chances of failure, just as far as they can be eliminated. The aim should be, therefore, first to give it information, and depend upon that and not upon any sentimental notion that a "property ought to be developed," in order to secure its co-operation.

The backbone of the mining industry to-day is the application of good business principles, sound economy and long experience to its conduct. Mining in its true sense implies science, industry and truth, exactly the same as

in part an effort to carry out the plan of the Miners' Association. It is gratifying to know that Congressman Newlands cordially responded to the wishes of the California organization. The bill meets his views and has his full endorsement.

Water Power and Electricity.

The cut on this page shows an application of Pelton wheels to electric generators by direct connection to the armature shaft. The wheels—four in number—are inclosed in two separate housings, all mounted on one shaft and connected to a 120 K. W. Westinghouse generator by an insulated coupling. They are 21 inches in diameter and have a combined capacity of 250-horse power, with a speed of 860 revolutions under a running head of 340 feet. The wheels in the plant here referred to require to be of

WATER POWER AND ELECTRIC GENERATORS.

lic is more and more to estimate accurately the value of things—to sift the real from the unreal. The design of the distributors of these large statements is always to attract the attention of the investing public to the merits of a particular district or a particular mine, and, incidentally, to avoid any possible chance of their light being hid under a bushel. But the public has become callous to that sort of thing, and it is more than ever difficult to secure attention by the statement of mere generalities.

In the nature of things it is hard to give complete and reliable data relative to any new mining proposition; indeed, it is practically impossible. But, so far as they go, the facts ought to be stated with care, the conditions and surface indications explained with an approach to accuracy and modesty, and the inferences drawn with prudence. Stereotyped expressions as to the "vast opportunities for investment of capital," "immense returns certain to accrue," "double your money in a year," "the opportunity of a lifetime," and all that kind of stuff, carry no weight. Many newspaper articles pretending to give an account of the undeveloped resources of the district in which they are printed use as their text the chances capital has long neglected by overlooking their merits. Such injudicious generalities too often precede and overshadow a narration of the facts, results, conditions, history and actual state of development. These should be the essence of such articles. The appeal to capital, if made, should be incidental,

any other legitimate pursuit. Adventitious circumstances sometimes permit the inexperienced miner to make a "strike" and a fortune; but the days of old, the days of gold, the days of '49, are fast becoming little more than a glorious memory, where luck ran rampant through California, and touched the tenderfoot and the old-timer alike with its golden rod. Conditions are different now, and it is necessary to place some of the pioneer methods in the background.

It may seem curious to many that the California Miners' Association has deemed it best to ask a Nevada Congressman (Mr. Newlands) to present to Congress the mining bill framed by its special committee appointed for that purpose. There were several good reasons for this action. It is desired above all things that the measure meet with the endorsement of the mining States generally, and to that end the interest and support of their various representatives must be solicited. The bill is not local in its provisions, and suggestions from various committees looking to its amendment have been expressly invited. It is to be hoped that the measure in its final shape will be recognized for all it designs to be—corrective of many inequities, ambiguities and even injustice of present law and present interpretation of law affecting every part of the great West. The selection of Congressman Newlands, whose devotion to mining interests is widely known, was

this small diameter to give proper speed to the generator under the head in this case available. A slower speed generator or a higher head of water would have admitted of larger wheels, and consequently a less number to give the same power.

The plant here shown is that of the Standard Con. Mining Co., of Bodie, California, and is one of the most interesting applications of electric transmission of power yet made in connection with mining operations. The power is transmitted 13 miles with a loss of only about 20 per cent, and affords a saving to the company of some \$25,000 a year in running expenses.

This installation illustrates the practicability of electric power transmission as well as the extraordinary saving which may be effected by utilizing a comparatively small water power though such a distance from the point where it is to be used. It also illustrates the extreme flexibility of the Pelton system and the facility with which adaptation can be made to all varying conditions.

The Pelton differential automatic governor shown on the left is designed to insure absolute and most sensitive control—maintaining a uniform speed on the wheels with instant and wide variations of load.

MARCUS DALY of the Anaconda has ordered reductions in wages ranging from 10 to 35 per cent on all classes of mining labor.

THERE are now 54 producing mines at Johannesburg, is reported by the Witwatersrand Chamber of Mines in the December report. Of the number, 50 have stamp mills, the largest having 160 stamps and the smallest 10. The total number of stamps running is 2175. The average amount of ore crushed per stamp was 3.65 tons per 24 hours. The average yield per ton under stamps was \$7.92; total tonnage crushed, 210,168. Six of the mills make concentrates before stamping, and all of them concentrate tailings from the stamps. Three of the mills use chlorination to work their concentrates, though the same mills use the MacArthur-Forrest process on their tailings. The concentrates carry from \$19 to \$60 per ton. The tonnage worked by the MacArthur-Forrest process was 136,900, and the yield per ton was \$7.50. The value of the total yield for December was \$2,490,000.

A CORRESPONDENT having questioned a statement of the *Territorial Enterprise* that \$60,000,000 of tailings from the Comstock lies buried in the Carson river, that paper proceeds to back up its assertion with the assertion that the mills have saved only from 60 to 85 per cent of the assay value of the ore, and that the total output being \$550,000,000 the loss was at least \$60,000,000. The *Enterprise* rather overstates some of the facts, so far as they have been determined by good authorities. The accepted estimate of the total Comstock output is \$350,000,000. It is difficult to tell what the loss has been, but it is not generally believed that it is so great as \$60,000,000. However it is very great, and the Carson river bed is covered for many miles with a great mass of debris containing gold. The trouble has been to get it out. It is not hoped, even under the most successful efforts, that more than a fraction of the great value deposited there will be secured.

It seems to be difficult to arrive at the facts of the Cripple Creek strike. Last week it was announced that the miners had won, and that several mines had resumed. Now, however, we are told that there is no change in the status of affairs. To-day (Thursday) was set by the principal mine-owners for resuming on a nine-hour basis. A temporary injunction has been granted by Judge Downer of the District Court restraining the members of the various miners' unions from interfering to prevent men from working. The sheriff is at the camp, with instructions to enforce the order of the court at whatever cost. Some of the most radical members of the union say that they will fight the sheriff and all the National Guard if necessary to prevent men from working nine hours. If the mines resume with a full force, as it is claimed they can, it will give employment to from 600 to 800 men. The trouble is really very serious. It has practically paralyzed Cripple Creek, which was an active and promising camp. It is to be hoped an early and amicable settlement will be reached.

The New Wilson Bill.

The Wilson bill, as it passed the lower house of Congress, bids fair to be materially modified by the Senate. The Democratic members of the Senate Finance Committee, after having considered the measure for a number of days, have laid it before the full committee, and in substantially the same shape it is certain to go before the Senate. In some respects the amended bill is an improvement, but in others the same objections obtain as were formerly urged. The particulars in which western mineral interests are affected, and in which changes are suggested by the committee, may be enumerated as follows:

The amended bill makes the duty on iron ore 40 cents per ton, and it is free under the Wilson bill. Pig iron, spiegel Eisen, etc., are taxed at 22½ per cent., and the Wilson bill duty is 20 per cent.

Iron slabs, blooms and other forms more advanced than pig, and less finished than bars, 25 per cent; Wilson bill, 22½.

Lead ore and lead dross, three-fourths of one cent per pound; provided that silver ore and all other ores containing lead shall pay a duty of three-fourths of one cent per pound on the lead contained therein, according to the sample assay at the port of entry.

Miscellaneous metal articles not otherwise provided for, 30 per cent; under the Wilson bill, 25.

Coal—Bituminous and shale, 40 cents per ton; coal slack, 15 cents per ton; cokes, 15 per cent ad valorem.

The bill as now presented fixes the duty on boracic acid and refined borax at 20 per cent in each case; in Wilson bill boracic acid is on the free list.

So far as California is concerned, free coal and free iron are wanted; and the change may be regarded as not beneficial to California interests. But the State of Washington is found to take quite a different view of the matter, and to regard it with favor.

The concession made to the lead and lead-silver interests is material. In fact, there is a complete change in the policy of the bill in this respect, in that the ad valorem feature is abandoned and the specific duty of the existing tariff restored. Under the Wilson bill it was proposed to impose a duty on lead dross of 15 per cent ad valorem, and to allow all lead in ore which is higher in silver value than lead to come in free of duty. The value of lead dross at Mexican ports of entry is not above 1½ cents per pound, and the average duty would therefore be about 1-5 cent per pound. It is evident that the abuses of the old half-and-half system were urged upon the committee and were influential in bringing about the change. It is well known that under the operation of the former provision the effort of importers is to convince customs officers that ore is more valuable for silver than for lead, and that there is in consequence strong incentive to corrupt practices. The Wilson bill pretended to impose a tariff of 1 cent per pound on all ore more valuable for lead than for silver; but the ½-cent duty on lead all around will, we believe, be a great deal more satisfactory, and in its actual operation will be more effectual and more remunerative to the Government than the 1-cent duty. In our judgment, the lead-silver interests of the United States are distinctly the gainers by this amendment.

Nothing has been done for quicksilver or petroleum.

Of course, the bill has not been accepted in its present shape by the Senate. All opinions as to its fate there are mere guesswork. It will certainly meet powerful opposition, in its entirety and in its special features; but the chances seem to favor its passage, notwithstanding the reported defection of several members of the party pledged to support tariff reform. It must be remembered, however, that the amendments of the Senate, if made, must still be concurred in by the House, which declared overwhelmingly for the Wilson bill.

The Chilean Exposition.

The following dispatch from Washington, under date of March 14, is of importance to mining men:

Secretary Gresham has written a letter in which he recommends to Congress that at least \$5000 be appropriated to enable this Government to participate in an exposition of minerals, mining machinery and metallurgy that is to be opened at Santiago, Chile, in September next. Our Minister, James D. Porter, has written to the State Department, setting forth the advantages to be gained by taking part in this display.

The director of the Geological Survey says officially that it would be desirable to enter into the exposition, and that a reasonably satisfactory display might be made for the amount recommended. The Chilean government is making great efforts to create a successful affair out of the project, and is meeting with much success. Senor Don Anibal Cruz, first secretary of the Chilean Legation, speaking for Minister Gana, said to-night:

"We wish to aid in opening up the vast mineral resources of our country by inviting the attention of foreign capital to the great wealth which awaits development, laying bare in our mountains. We want to show our people the advanced methods of mining and modern machinery

of the latest type, so that they may be led to discard the old and primitive methods for new and more profitable plants. Mining in Chile is in some places carried on with machinery from abroad that will compare favorably with that of many countries, but for the most part our plants are moderate in size and of such fashion that a comparatively small portion of the value of the ore is recovered. There are enormous bodies of tailings in various parts of Chile which, if worked over by modern machinery, would yield safe and sure profits of great value.

"Naturally we look to America as the nearest and most desirable point from which to obtain mining machinery of the latest and most improved pattern. We expect to consume great quantities of it in the years to come, but so far America has shown but little inclination to push its trade with us in this line, and we have bought large plants from Great Britain. To show you the extent of our project I will say that we have appropriated \$150,000 for the initial expenses of the enterprise. This put into buildings means as much as \$250,000 in America, where labor and materials are so dear. We have invited all the nations of the earth to take part, and we are already receiving applications for space from manufacturers and other interested persons in America, even from Canada. Our government will pay the cost of conveyance by land or sea, or both, of all exhibits, and in the case of such as are not sold within one year from next September will send the exhibits back home free of charge.

"While in Chile goods will be regarded as in private bond, and no duty will be collected upon them unless they are sold or left in our country over one year. We also bind ourselves to pay the passage money of all such operatives as it may be necessary to bring out, erect and run the machinery exhibited—not only to Chile, but home again. We will furnish free motive power, tables and show cases, so that the cost of installation will be only the necessary expenditure connected with exhibits.

"We shall give medals of three classes, and every effort will be made to have the awards fairly made. Each jury will consist of three Chileans and two foreigners, and there will be a court of appeal. The precise date when the exposition will be opened is not settled, beyond that it will be in September. It will run for six weeks or more. Applications for space should be addressed to the Chilean Legation at Washington, D. C.

"We have watched with great interest your big Midwinter Fair in San Francisco, and we congratulate you on your signal success. It reflects great credit on your people. We hope that some of the mining machinery exhibited there, which we believe is of California manufacture and equal to any made elsewhere, will find its way to Chile."

An Important Decision.

The United States Supreme Court has rendered a decision in a Montana mining case which may be of great importance. The full text has not been received, but the gist of the decision is contained in the following telegram from Washington to a Butte lawyer:

Court reverses. Holds any side line is end line. Directs partition, or if that impracticable, sale and division proceeds. No dissent.

This decision affects the Non-Consolidated-Amy & Silversmith controversy. Until the full opinion is received, just what effect it will have on a number of important mining lawsuits now pending cannot be determined.

In the case just concluded the court holds that what the Amy people claimed were the side lines of their location are the end lines. It is a well-settled proposition of law that a miner cannot go beyond a vertical point of his end line in following the dip of his vein, but he may follow it, on its dip, beyond the side lines to any depth. That this may be better understood, the diagram below is referred to:

The Non-Consolidated lode is a small claim at the north-west end of the Amy & Silversmith. The line drawn diagonally shows the course of the Amy vein as indicated on the surface. The long lines, which run east and west 1500 feet, are what have been the accepted side lines of the Amy lode. The vein dips to the north into the Non-Consolidated; and by the Supreme Court decision, the Amy people have no further claim to the vein beyond the point where it passes beyond the north line.

As several lawyers about town understand it, this decision does not affect locations made upon the vein for a distance of 1500 feet. In the case of the Amy, however,

it appears the location was made only 600 feet along the vein. When the location was originally made, it is evident the course was thought to have been due east and west, and not northeast and southwest, as later development proved.

It is believed there are not a great many locations of this nature, hence the decision may affect only such locations as cut across the vein instead of running parallel with it. Where the apex of vein is shown on the surface, the survey line, that crosses the apex, becomes the end line, whether it is marked as the side line or end line. This is believed to be the correct interpretation of the decision.

California Mines at the Midwinter Fair.

Nevada County.—Greater space has been assigned for exhibit of the mineral wealth of this county than any other, for the sufficient reason that it is the largest and most important district in the State, in point of output, though it has several good seconds. If the energy and judgment displayed in gathering this exhibit are a criterion of the activity of Nevada county's mining men generally, they are likely to maintain their prestige for some time to come. The location is in the northeast end of the Mineral Division, Mechanic Arts building, fronting the northeast aisle, and extending from the center aisle to the northern aisle. The exhibit is really a fine one. An idea of its extent may be obtained when it is stated that something like 60 tons of ore alone are one of its conspicuous features. The value of the exhibit lies in the fact that it is representative of mines actually working, showing all varieties of pay ore from depths of 500 to 2000 feet, and designed further to illustrate the extent of the workings and the strength and permanence of the lodes in the several Nevada mining districts. The largest single piece of ore is from the Osborn Hill mine—a property abandoned for many years, by the way, but of approved merit and now prosperous. It weighs 3000 pounds. Other pieces of all weights less than the maximum figure are shown from about 30 operating mines.

One interesting thing is a mass of ore from the famous Idaho-Maryland mine, showing the width of the vein, pieces of the hanging and foot wall being attached to the quartz. In a glass case is also exhibited a piece of quartz, weighing several hundred pounds, from the Maryland extension of the Idaho which took first premium at Chicago as the finest specimen of California gold ore. It is shown by S. P. Dorsey, now principal owner of the Idaho-Maryland. In this connection, Mr. John A. Coleman, of Coleman Brothers, has just furnished Mr. Chas. H. Mitchell, who is in charge of the exhibit, an exact statement of the Idaho mine from 1869 to 1894, under the Coleman proprietorship. The total yield was \$11,639,360, out of which 279 dividends were declared, amounting to \$5,074,700. It is well known that the old Eureka, the Idaho and the Maryland properties adjoin on the same lode. The former produced \$3,500,000, and there is every indication that the Maryland will do as well, making the Eureka lode by all odds the richest in the United States.

The North Bloomfield mine displays a model of what was probably the largest gold brick ever cast from one run in California. The weight is 6,117.78 ounces troy; fineness, .897; total value, \$114,280.72. The cleanup was made shortly before the mine shut down, by order of the courts.

In two glass cases, occupying a conspicuous position, are shown in glass ore in its various conditions from the time it leaves the battery until it emerges in gold bars. These exhibits are by the Champion mine of Nevada City, and Omaha Consolidated, of Grass Valley. There are shown successively pulp from batteries, sulphurets, sulphurets after roasting, gold in solution, gold precipitated, tailings, amalgam balls, gold bar. Besides these, the Omaha shows in one jar pure quartz, copper pyrites, iron pyrites, sulphurets from concentrator, tailings, gold in quartz, pulp from battery plates, sulphurets after roasting. These altogether make a very instructive and attractive display.

The copper exhibit of the Imperial Paint and Copper Company of Spenceville is complete. Its chief features are cement, copper and mineral paint, besides copper, ingots and copper in various solutions. Fine views of the mine and surface works at Spenceville also appear.

A 2700-pound specimen of hematite iron ore from Indian springs, nine miles west of Grass Valley, attracts much attention. It contains 54 per cent iron. No attempt has been made to develop the deposit, and there is no prospect that there will be as long as English and Puget Sound vessels bring pig iron to this port in ballast at a very low figure.

A sedimentary stone from Truckee basin is called fire-proof building stone. It is said to outlast two sets of fire brick.

Black marble from near North Bloomfield is shown. It

takes a high polish, and looks like it ought to have commercial value.

In the way of the curios, a large collection of petrifications from You Bet is displayed. One very interesting petrification is a brook trout, six inches long, firmly imbedded in petrified wood. It was found 100 feet underground.

The showing of auriferous gravel from Nevada City, North Bloomfield and other places is not yet complete.

Mention of the great gilded globe, designed to show the bulk of Nevada's gold output, should not be omitted. It occupies a central position in the exhibit, and from its size and color elicits a great deal of favorable comment. The ball is 10.4 feet in diameter and contains 629.59 cubic feet. It is an exact representation of a gold mass worth \$205,000,000, which, according to conservative estimates, is Nevada's gross gold output.

The exhibit is in charge of Mr. Charles H. Mitchell, under whose supervision it was collected, and who is always at his post ready to explain its various features and merits. A summary of the exhibit is as follows:

Quartz from the following mines: Idaho mine of Grass Valley; the Maryland, on the same lode; the Omaha, North Star, Original Empire, W. Y. O. D., Menlo, Osborn Hill, Perrin and Ben Franklin, Champion, Providence, Federal Loan, Spanish Mayflower, North Banner and Gold Flat, St. Gothard and Defiance, National and Mistletoe.

Other exhibits are: Copper ore and products, including copper paint and fire-proof mineral paint, mined and manufactured in the county; fire-proof building stone from Truckee; stone furnace lining and black, polished marble from North Bloomfield; model of the largest gold brick ever cast in the State (\$114,280), the product of one run from the North Bloomfield mine; gold-bearing cement, gold-bearing gravel, wood petrifications and mineralized gravel from the same mine; gold-bearing gravel, fine gold, iron pyrites, clays and wood petrifications from the Odin gravel mine of Nevada City; copper and gold-bearing ores from the Bulwer mine; copper ore from the Jackson mine; wood petrification from You Bet; high-grade copper ore from the Bull Run mine of North Bloomfield; gold-bearing quartz from the German mine in the Washington district; prize piece of gold ore at the World's Fair at Chicago from the Maryland mine; models of gold specimens and bricks, amalgam, pulp, concentrates, raw and roasted sulphates, gold precipitants and chlorine gold, showing the process of gold extraction from the ores; hematite iron ore from Indian Springs; crayon drawing of underground workings of the Merrifield mine at Nevada City; photographs of the Federal Loan mine, the North Bloomfield dam and mine of the Copper Paint Works at Spenceville, of the Champion mine and of the Omaha Consolidated mine.

Mono County.—Two huge gilded blocks surmount an arch leading into the exhibit of Mono county. They represent respectively the gold and silver outputs of the county and are appropriately lettered. The silver yield is 4,000,000 ounces, the gold 1,433,000 ounces, or \$26,120,000. The location of the exhibit is in the western part of the mineral section.

The exhibit, as a whole, is small, but choice. A leading feature is a number of slabs of travertine, said to be from the only quarry of the kind in the United States. It was discovered last fall by W. E. Lindsey of Carson City, Nev. The location is one mile from Bridgeport. The travertine is highly colored and susceptible of a fine polish. An effort is to be made to develop the deposit.

Models of the workings of the Standard Consolidated and Bulwer Consolidated mining claims, above the 300 levels, are shown. A number of views of the electric plant of the Standard are suspended from the walls. A size model of a double-deck mining cage with safety clutch, made by Andrew Smith, attracts the visitor's notice.

In the way of curiosities, the most noticeable thing is a section of a tamarack tree, in which is partly imbedded a pair of deer's antlers, said to have been hung across a limb by the Fremont party, in Lost canyon, 1845.

In detail the exhibit contains:

Gold quartz from the Charleston mine in the Mono lake district; gold quartz from the Jackson and Lakeview mine in the Homer district; gold ore from the Golita mine in the Jordan district; gold quartz from the Bulwer Consolidated mine in the Bodie district; gold ore from the Standard Consolidated mine in the Bodie district; gold quartz from the Josie Green mine in the Homer district; silver ore from the Patterson mine in the Patterson district; gold quartz from the Bodie Consolidated mine in the Bodie district; copper ore from the Golita mine in the Jordan district; model of the Bulwer Consolidated mine; model of the Standard Consolidated mine; model of square-set timbering; model of mining cage, patented and owned in the county; pictures of mining scenes, 37 views; full set of mining tools in miniature; specimen cases of gold, silver, copper, sulphate of iron, petrified wood, quartz, crystals, flint arrow heads; specimen case of free gold, and nuggets from the Dogtown, Big Emma, Bonanza, South Bulwer, Bodie, and Golden Prince mines, in the Mono Lake district; building rock of lava formation, Mono lake specimens; section of a tree from Lost canyon, in which a pair of deer horns were hung 45 years ago by the Fremont party; sun-burned travertine, found 7000 feet above the sea level; agatized plant.

There is nothing satisfactory in the smelting situation in Colorado, or for that matter anywhere in the world, says the *Denver Mining Industry*. The decline in the price of silver is reducing the ore supply very rapidly. This means a great reduction in the product of the smelters, while expenses are not, and cannot be, reduced to correspond. The smelting companies have gone to the extreme limit they can go in reducing smelting charges in order to encourage greater ore production by miners. A further reduction would mean increased losses, and probably every concern would prefer to go out of business rather than to risk them.

Slitkens.

The Congress mine, near Prescott, A. T., has been sold for \$1,500,000, so it is said.

The new Everett, Wash., smelter made its first shipment of 30 tons of bullion to San Francisco on March 1st.

The Standard Con. Mining Company has paid a dividend of 10 cents per share. The company had over \$40,000 on hand on the 1st. The dividend will take \$10,000.

The February report of the De Lamar Mining Company, whose product is three-fourths gold, shows a total production of \$82,330; estimated profit, \$46,139.

"CAPTAIN GOLD," the Hydah Indian who discovered gold on the islands near the British Columbia coast, died at Skidegate some weeks ago. His title was given him because of his discovery.

The upper Kootenay papers are awakening to the necessity of building concentrators, as, for every ton of high-grade ore shipped out, a dozen tons of proper food for concentrators are exposed.

The Utica Mining Company at Angels, Calaveras county, has begun the erection of a private hospital for its employees. Trained nurses will be in attendance and every comfort will be provided for sick and injured miners.

Excitement prevails at Needles over the new gold fields at Goldstone. Assays from five claims show from \$175 to \$1100 in free gold per ton. Rich strikes are also reported from the desert country 60 miles from San Bernardino.

STATE COAL MINE INSPECTOR REX of Colorado has returned from a tour of inspection of the mines in Las Animas and Huerfano counties. He did not find a single mine where the wages of miners were not from two to five months in arrears.

The Boston & Montana Company has announced a dividend for March of five cents per share. This company's annual report will soon be out and it is announced it will show that the company can produce copper as cheaply as any company in the country.

Work was suspended by the Anstin (Nev.) Mining Company last week on account of litigation against the company. This throws about 100 men out of employment, many of whom have large families. Efforts are being made to make an amicable settlement of the dispute, so that work may be resumed.

ARTICLES of incorporation of the Hecla Mining and Milling Company have been filed at Grass Valley. The company is incorporated with 100,000 shares, of which 40,000 have been subscribed. The directors of the company are J. C. Roberts, D. N. Coffin, W. A. Hawley, Wm. M. Blair and John Roberts. The Hecla mine was formerly known as the Kate Hayes mine.

A GOLD-BEARING ledge has been struck a short distance east of Truckee which prospects very well and has every indication of being a rich find. The ledge is quite large, and already several tons of rock have been extracted from it, every piece of which shows well in free gold. As the owner has sunk but a short distance, it is not known yet whether the ledge increases or decreases in richness and size as it goes down. Truckee is basing better times on the find.

The annual meeting of stockholders of the Hale & Norcross Mining Company was held Wednesday afternoon in the Nevada block. The amount of stock represented was 105,390 shares. Following were the officers elected for the ensuing year: President, Nathaniel Messer; vice-president, W. S. Lyle; secretary, A. B. Thompson; superintendent, Joseph R. Ryan. The report of the secretary showed \$12,353.92 on hand at the end of the year, February 28th.

MR. JOHN TRELOAN has resigned the superintendency of the Wildman mine, Amador county, the resignation to take effect on the first of April. Who will be his successor is not yet known there. Mr. Treloan has had this step in view for some time and was only deterred from resigning several months ago by the earnest wishes of the company that he continue in charge. He retires to enjoy the repose earned by over 60 years of active service in mining operations.

The Eureka mill on the Carson river is making a final clean-up and will cease operations altogether, says the *Dayton Times*. It is rumored that some Chicago people have purchased all the tailings owned by the Nevada Mill and Mining Co., and that a new process will be introduced to work them in the near future. There is not much hope, however, that operations will be resumed with silver at 60 cents an ounce. The closing of the mill will throw a number of Daytonites out of employment.

A RECENT letter received by officer Bowman at Virginia City from George Sanford, now located at Montgomery, down in the southern corner of Nevada, on the border of Death Valley desert, gives a favorable account of that district. The writer says the nearest store is in Vanderbilt, 110 miles away. He broke his pipe on the trip there and could not replace it without sending to Vanderbilt. He says there is lots of gold in Montgomery and a stamp mill is about to be erected there. Miners receive \$4 a day, but the price of living is high.

The *Vale (Or.) Gazette* says that quite a good deal of interest is being manifested in the gold fields on Snake river, and many of the citizens of Vale and vicinity are now going over there with tents and lumber, preparatory to putting in the summer taking out the shining needful. The mines are a little over 20 miles from Vale, yet it is the nearest supply point for the energetic miners. At present about 35 men are working claims there, which pay from \$2 to \$12 to the man. The mines are old gravel beds, and the gold is flour gold that goes from \$17 to \$19.

The steamship Bawnmore, Captain Woodside, the first vessel that was ever fitted with tanks in San Francisco for the purpose of carrying crude oil in bulk, has left her anchorage in the bay and gone to Oakland to take coal from the Servia Cadena. She will start for Telara Bay, in Peru, on Wednesday to secure her first cargo of oil. The Bawnmore is under charter to Grace & Co., the charterers agreeing to make all the alterations in the vessel; to guarantee 2865 tons of oil each voyage, for which they guarantee to pay \$4.20 per ton, a five-days "lay" being allowed at each port. There are 14 huge tanks for carrying oil, and the steamer is fitted with every precaution against accident.

River Mining in Sierra County.

Slightly Abridged from Correspondence in the Downieville Messenger.

There is no doubt that many rich bars or banks still exist in rivers, gulches, creeks and ravines in all the mining counties of this State. From some of the numerous auriferous streams of Sierra county fortunes are extracted by their industrious owners, of which very little is known to the outside world. In many instances they work over the tailings that are run annually down from the surrounding mines, yielding a handsome profit every year. The well-known Slate Creek basin, Slate and Canyon creeks, and their tributaries, have yielded millions and millions of dollars by working them over and over again. From Rock creek, below Scales, several hundred thousand dollars have been taken out by the lucky ones in working the tailings over that are poured in there more or less every year from Scales, Union Hill and Fair Play. All branches of Canyon creek above Poker Flat, and those of Slate creek, have yielded fabulous sums of gold, of which wonderful stories are related by the few remaining pioneers of the early days while mining was flourishing.

The Slate creek bed has been worked but very little, as it was soon covered with tailings that are poured into it from the early-discovered, so-called hill diggings. It was only worked in shallow places, with insignificant appliances then in vogue, but with immense results. All those creeks fed the Yuba river, which became world-renowned in days gone by for its wonderful yield. The late Major Downie, the founder of Downieville, told that when once moving camp from the Yuba, to look for still richer diggings, the partners quarreled among themselves about who should carry the heavy gold dust in the heat of the day, when traveling over the mountains without trails or roads. Where tailings have been washed into these streams they are practically worked over again by innumerable small companies, in many instances under great difficulties, and all with more or less profit. Even at Bullard's bar, in the Yuba river, below the mouth of Slate creek, where the same has filled up with the lighter tailings from the great Slate Creek basin, they are now worked partially over and over again every summer, yielding from \$5 to \$25 a day, to each man, by shovelling and washing them in sluices, soon after the freshets have subsided.

On the Slate Creek basin we find two of the largest "river" or "tailing mine enterprises" of unquestionable richness in the bed of Slate creek that have been promulgated. One, commenced during the last year by Hon. J. W. Moyle, ex-State Senator of Sierra county, large stockholder of the Slate Creek Gravel Gold Company (Limited), an English syndicate formed by himself and friends in London in February, 1893, with a capital stock of \$500,000, to mine the auriferous rich tailing deposits and gravel beds, etc., in Slate creek. They control about two miles of the same above St. Louis bridge. After having prospected the accumulated tailings and finding a yield of from one-half to two ounces of gold a day to each man, they commenced last spring with a very large force of men to work and develop their recently acquired property, expending nearly \$100,000 last year in building a steam-power sawmill, a ditch over three miles long and more than five feet wide, and purchased a large supply of heavy iron pipes and varied expensive machinery of every description, said ditch to deliver water at its lower end into a pipe, whence it is carried through the same to the creek at St. Louis bridge, to be used under 275 feet pressure in connection with an immense hydraulic elevator, already on the ground near the St. Louis bridge, where General Superintendent Moyle commenced last fall with a smaller elevator to sluice out a large pit or sump in the once over 50 to 60 feet of deep of tailings to reach bedrock, on which to anchor the larger machine which is used to suck and lift the gravel from the bedrock into a flume set along on the Slate creek hillside, paved with blocks. This sump has reached a depth of 20 feet, but on account of the extreme cold weather at the head of the watershed everything froze up and operations had to be delayed until milder weather would permit them to proceed with their developments. They have built above this sump, across the creek, a substantial dam of log cribs filled in with rocks.

It is predicted that if this company is able to work this ground with these appliances and their outlined plan, they will take out more money than has been obtained from the best-paying mines in Plumas or Sierra counties, as these accumulated tailings and the original gravel in Slate creek are immensely rich in gold, as proven by Brewster and Haworth 20 or 25 years ago, when they owned a tunnel through the long point under the St. Louis road, enabling them, after drawing off to some extent the tailings for a short while at the upper end of said tunnel, yielding \$8 to \$25 a day to the man, shovelling tailings into sluices. The following season they were prevented from working any more, on account of the introduction and working of sev-

eral dozen monitors in the hydraulic gravel mines on the channels above them, soon burying the upper and lower ends of said tunnel, including bridges across the creek, out of sight.

What has been said about the richness of the valuable mining properties can be applied to the Alturas mine, below said St. Louis bridge. That mine is about three miles long, owned by Hendel & Packer, who already have expended over \$105,000 in trying to open the whole of Slate creek above them, from their lower end at the Port Wine bridge where they have been steadily, quietly and tenaciously at work, for over a quarter of a century, in blasting a long bedrock cut, of about 20 feet in width by 5 to 40 feet in depth, and excavating several large tunnels through projecting, long, sharp bedrock points at the bends or elbows of the creek, to busband the grade and obtain more fall for their bedrock ground-sluice or flume.

They worked successfully last year only late in the season with about 30 men by shovelling tailings and the creek gravel into iron buckets of an endless link-belt machine, manufactured in the East, to elevate the gravel into elevated sluices, all operated and washed by the same water, obtained through an iron pipe attached to one of their ditches. The tailings, after being washed, are dumped on the banks outside of the creek, thus giving them as they advance a good drainage to clean up the exposed bedrock crevasses in which the richest part of the claim is found, when the tailings and gravel have been reduced by the spring floods, and washed during the mining season. The buckets are twenty inches long and two feet wide, and have a half semi-circular shape. They are fastened eight to ten feet apart to the two parallel link belts. These belts glide along on rollers near the bedrock, enabling the men easily to shovel the gravel into the buckets as they silently and steadily move along up to a tower, where, in turning over a large drum or wheel, the gravel empties into a large sluice box underneath, and is carried along through the sluice, thus washing the gold from the gravel. This is a cheaper method of mining than has been done here before, when the gravel had to be shoveled high—two, three and four times over before reaching the elevated sluices, so that, after entering the creek again, men had to be employed to shovel and throw the washed gravel below the sluices into large piles to leave a drain open for the water at the workings and for the washings, all of which is now obviated. The links are 12 inches long, and are so constructed that they can be easily taken out or more added to the chains, if required, in a moment, as the workings of the bed of the creek may require. The tailings in this creek are 250 to 500 feet in width, and 5 to 40 feet, formerly 50 to 60 feet, in depth. This company worked a very small portion last year, the best of which yielded over \$5000 from only 100 square feet. Their pay-roll was more than \$8000 during last year. The gold averages over 900 fine. They will work this year two such machines, each one on very rich ground, that they have already developed, and as they will be in a better condition than ever before to work to greater advantage, they will give employment to 60 or 80 men this season. Creek tailings always proved very rich when they could be worked with advantage. Many fortunes were realized from the partial working of ravines, creeks and gulches that are tributary to the very little worked Slate creek, estimated by many to contain half as much gold as the channels above have thus far yielded. Hon. B. Barnes, ex-internal revenue collector, of La Porte, Plumas county, estimated that they have reached, to the end of 1891, the sum of \$132,132,000, as per his interesting communication made to the *Oroville Register*, published Feb. 25, 1892, in regard to the "Richness of Plumas County." He refers to the days when such mines as the Conly & Gowell claims, at La Porte, took out in one clean-up \$271,000; also that on the 18th of May, 1858, he accompanied F. D. Everts, of the express firm of Everts, Wilson & Co., when taking from La Porte on several mules \$250,000 in gold dust as only one of a tri-weekly shipment during the clean-up season. In those days Messrs. Cox, Knowles & Fant realized from tailings, in one season's work, over \$20,000 from a ravine below the Howland Flat mines.

That such river mines are rich there is no longer any doubt. Those of the Comstock are estimated at 20 to 40 per cent of the diggings worked in early days; for Slate Creek Basin, 25 or more per cent of the gold product of the gravel channels worked above them. If so, they would not amount to over \$33,000,000, in addition to the value of gold obtained in the original, which is incalculable.

THE MINING AND PROMOTING COMPANY.—Articles of incorporation of the "Mining and Promoting Company" have just been recorded here. The purposes for which the company is formed are to prospect, to buy and sell on commission or otherwise, to bond and lease mining properties, etc. The directors of the company are A. H. Rapp, M. E., president; General Charles Forman, vice-president; Hon. C. S. Young, secretary; Charles E. Shafer, C. E., and C. D.

Galvin, C. E. California Safe Deposit and Trust Company, treasurer. The main offices of the company are rooms 94, 95 and 96, Crocker Building, San Francisco. The other offices are: One with General Forman, Potomac Block, Los Angeles, and the other with C. D. Galvin, Esq., 26 Van Buren street, Chicago, Ill.

Locations on Mexican Land Grants.

Delegate Josef of New Mexico has introduced a bill to authorize locations of mines of precious metals situated in Spanish or Mexican land grants. The mineral-bearing parts of these lands are, by act of Congress, the property of the United States. The complication of rights is now such that neither the owners of the grants nor anybody else can develop the mineral resources of these grants. The bill reads as follows:

"Any gold, silver or quicksilver mines, or other valuable mineral deposits belonging to the United States, and situated within exterior boundaries of any tract of land held, claimed, allowed, confirmed or patented by the United States, to or by any person or persons, under and in pursuance of an act entitled 'An act to establish a court of private land claims, etc.,' approved March 3, 1891, and hereby declared to be free and open to location, working and purchase by citizens of the United States and those who have declared their intention to become such, and in the same manner and subject to the same laws and regulations are or may be applicable to mineral deposits in lands belonging to the United States.

"In case the claimant or owner of any such land under any grant from Spain or Mexico, allowed, confirmed or patented by the United States, shall not consent to the location, working and purchase of any such valuable mineral deposits as aforesaid by the discoverer or locator of the same, and to the reasonable and necessary rights of ingress, egress and occupation of and upon the said land in which the mineral deposits are situated, for the purpose aforesaid, it shall be lawful for such owner or claimant of said land to bring suit in any court of general jurisdiction within which the land is situated against such discoverer, locator or possessor of such valuable mineral deposits, for the recovery of any damages to land occasioned by such location, working or occupation of the same, or by such ingress and egress to and from the same over the said land. But such right of action shall not be construed to authorize such claimant or owner of said land to prevent or interfere with the occupation and working of any such mine or mineral deposit, provided the discoverer, locator or possessor of the same shall give bonds, with sufficient sureties, in such amount as the court may direct, to such owner or claimant, conditioned for the payment of such damages to said land as may be recovered in such action.

"All acts or parts of acts in conflict herewith are hereby repealed."

Chrome Cast Steel.

One of the busy establishments of the times is that of the Chrome Steel Works of Brooklyn, N. Y., whose product is the well known chrome cast steel. The abundance of orders which has kept these large works running full time with full number of hands during the past year, despite the lengthy period of general trade dullness, speaks volumes for the high favor which this material has obtained in this country.

Chrome steel differs essentially from ordinary steel in the substitution of chromium for carbon in its manufacture. It is very hard, tough and dense, will not deteriorate by the continued application of great heat, and can be worked successfully in large masses. These qualities adapt it specially for the manufacture of such castings as gears, wheels, pinions, hammer dies, etc., for general machine construction. Its use in this connection is extending rapidly.

Chrome steel is also particularly well suited and desirable for the manufacture of castings for stamp mills for mining; in fact, reports of its use for such work are flattering in the extreme. Many mining companies throughout both North and South America have discarded the use of iron or ordinary steel battery-shoes and dies, cams, tappets and hoes, crusher-plates and roll-shells, which they have heretofore been using, for those made of chrome steel. The shoes and dies that are made of this particular kind of steel, it is claimed, will not cup; neither will the shoe break at the shank. They will, moreover, wear evenly from end to end, thus crushing more ore than shoes and dies of iron, which, as all millmen know, wear irregularly and are in the main short-lived. The State Mineralogist of California, in his eighth annual report, says of chrome cast-steel shoes and dies, as used in the Patterson mine (page 656): "One set of iron shoes and dies lasted six weeks and crushed about one thousand six hundred and eighty (1,680) tons, while one set of chrome steel shoes and dies is said to have lasted fourteen months, and wore even, which indicates a crushing of sixteen thousand eight hundred (16,800) tons, or just ten times the amount crushed by iron."

In addition to the foregoing, we notice the following in an annual report made by the president of a prominent gold mining company of Nova Scotia, viz.: "The shoes and dies of chrome steel, made by the Chrome Steel Works of Brooklyn, N. Y., have done admirable service, being replaced only after crushing 3,300 tons of quartz ore. From data of other gold mills at hand this would seem to show a remarkable capacity for work, and not either on account of the softness of the ore, for, on the other hand, the quartz is fairly hard and sharp."

A combination welded chrome steel and iron five-ply plate is another popular form in which chrome steel is furnished. These plates have been used for years past in the construction of safes and vaults of the largest financial institutions throughout the country. They are absolutely burglar-proof, for no tool, no matter how finely made and tempered, can cut, drill or saw them. They are composed of alternate layers of chrome steel and iron, welded together.

Every one interested in the economical use of castings and the construction of burglar-proof work should investigate the merits of chrome steel products, if they have not already had their attention drawn to this really wonderful material.

Mr. H. D. Morris, 220 Fremont Street, San Francisco, Cal., is the agent of the Chrome Steel Works on this coast.

The Red Point Drift Gravel Mine.*

By C. F. Hoffmann, Mem. Tech. Soc'y.

In Three Parts.—Part II.

The gold is mostly in the form of what is known as "scale gold," consisting of flakes resembling fish scales, or the scaly particles in bran. In places, however, there are streaks of coarser gold and occasional nuggets of one or two ounces weight.

Size.—A number of "cleannops" were passed through a series of sieves of different meshes to determine the percentage of coarse, medium and fine gold. They were included under the heading:

Coarse Gold.—All that will not pass a sieve of 10 meshes to the inch. There are required from 600 to 700 of the finer colors of this class to weigh one ounce, and in these are included all colors, from the weight indicated up to the largest nugget.

Medium.—The remaining part that will not pass a 20-mesh sieve. This is more scaly and uniform in size, average 2200 colors to the ounce.

Fine.—The remaining part that will not pass a 40-mesh sieve, average 12,000 colors to the ounce.

Powder.—The remaining part having passed the 40-mesh sieve, colors too fine to count, average 40,000 or more to the ounce.

The following are the percentages by weight: *Coarse*, 15.78 per cent; *Medium*, 48 per cent; *Fine*, 36 per cent; *Powder*, 0.32 per cent.

Value.—The gold varies in fineness (purity) from .928 to .937, and the ounce is valued at \$18.90 net. The purest gold has been found where the largest streams of percolating water were encountered in the gravel breasts.

Distribution.—The distribution of the gold in the channel is very irregular. Most of the gold is found on the bedrock. In some sections, however, it is mainly in the gravel above. The richest spot in this mine was found in a layer of gravel from 6 to 12 inches above the bedrock. At this point the bedrock was hard and smooth, and the channel straight. Some of the gravel was scraped up by hand, and contained as much as 33 ounces to the pan. For two months the average yield was \$7.50 per carload of 22 cubic feet. It appeared as if the gold had been carried by a freshet which spent its force at this particular place.

Again, the gold is found in paying quantities in an upper layer, from 40 to 10 feet above pay streak on the bedrock. There is one rule which applies to this channel, and perhaps to others with beds of stratified rocks. The consecutive strata having different degrees of hardness will form riffles, so to speak, along or across the channel according to its course. Now, when the gold dust strikes these riffles it is washed along them in the direction deflecting least from the course of the stream and concentrates toward the rim. If it strikes at right angles it lodges in the center, or scatters to the right and left. (See Fig. 1.)

Fig. 1.

This rule holds good for the main bodies of pay gravel. Of course, if the bedrock is once covered it no longer governs the travel of the gold in this way, and this rule applies only to the pay streaks on the bedrock. In these main bodies the quantity of the gold again varies very much locally. It is generally found more abundant in cracks formed by the cleavage of the rock, at right angles with the strike, also around quartz veins, which are rough on the surface and hold the gold more readily, or where the slate is soft and thinly foliated. The gold dust will lodge in small pockets or pot holes and in cracks, to the depth of a foot or more. The lowest run in the channel contains very little gold, sometimes a little coarse gold, but the bulk of it is thrown on the sides or higher rock. It is also found more plentifully on the down-stream side of islands and very large rocks.

SYSTEM OF WORKING.

A main gangway is run as near as possible in lowest part of the channel, avoiding turns as much as possible. Cross cuts are run from this gangway every hundred feet, if practicable, toward each rim. They are not driven at right an-

gles to the channel course, but diagonally across it, so as to avoid cutting too much bedrock to keep the grade down. Arriving near the rim, where the bed raises rapidly, the grade is abandoned, and the rock followed up high enough to make sure that the true rim is reached. Generally the rim is indicated by sand and fragments of loose bedrock (float). The bedrock is so uneven and steep in places that car tracks on a higher level become necessary to facilitate the delivery of the gravel from the breasts to the cross cuts or gangway. These are about four feet above the normal grade, high enough to dump from one car into another. The cars running on these higher levels are of smaller size. In some places wheelbarrows are resorted to, and this makes the extraction expensive. The main gangway is kept ahead of the breasts as far as possible, and most of the breasting is done from the cross cuts and small car tracks. Blasting occurs only twice a day, at noon and 11 P. M., just before meal times. The roof being firm cement, no lagging is needed in timbering, only posts and caps are required. The posts, measuring not less than ten inches in diameter, are placed from six to eight feet apart, and sills are put under them where the bedrock is soft. Natural pillars of gravel are occasionally left along the sides of the main gangway and cross cuts, and at other points when the channel is wide. About one-third of the gravel consists of boulders exceeding five inches in diameter, and these are not removed from the mine, but are used in building walls between the timbers along the sides of the gangway and cross cuts to give further security against flaking and caving of the roof.

VENTILATION.

Heretofore the ventilation of the mine has been accomplished by a No. 4 Baker blower run by steam power, requiring 7.5 indicated horse power. However, quite recently a second blower (No. 4½ Baker) has been introduced. This is attached to a Pelton wheel, and will be run by water power for at least six months in the year. The air pipe used is eleven inches in diameter, and only one such pipe is required for ventilation, excepting where the channel is very wide. In such places a seven-inch distributing pipe is carried into the breasts, but usually the cross cuts and connections cause a sufficient circulation without such aid. The monthly cost of ventilation by steam power is as follows: (Average of six months.)

Two engineers at \$3.50.....	\$193 00
Thirty-three cords of wood at \$2.87.....	94 71
Oil, 6½ gallons.....	4 60
Eighty feet of new 11-inch pipe at 46 cents.....	36 80

Total.....\$329 11

This shows for 3064 carloads, 17 cents per carload.

TRANSPORTATION.

Four horses are needed for the transportation of the gravel, two on the day shift and two on the night shift. One extra horse is kept for reserve. One horse takes a train of six cars through the gangway to the chute, where the gravel is dumped. From the bottom of the chute, in the bedrock tunnel 44 feet below, the gravel is drawn in a train of ten cars, and the second horse takes it out to the dump house. The channel cars are iron dumpers of 22 cubic feet capacity. The tunnel cars have the same capacity, are also of iron, but the front ends are inclined and they are not dumpers. The latter are run out to the surface on to a self-dumping chair designed by Mr. H. C. Bebr. The chair turns upon an eccentric axis, and the gravel is dumped to the wash-log floor 30 feet below. The driver does the dumping. Each train has a break car attached to it. The total distance from the breasts to the dump house is 6514 feet, or nearly 1.25 miles, 3273 feet being in the channel gangway, and 3241 feet along the tunnel to the surface. The number of cars used in the mine at present is 30. The monthly cost is as follows: (Average of six months.)

Feed for horses.....	\$62 50
Wages of four drivers, at \$3.....	324 00
Wages of two Chinamen, at \$1.75.....	98 00
Car wheels, oil, etc.....	20 00

Total.....\$504 50

This gives for 3064 carloads 16 cents per carload.

COST OF LABOR.

The average cost of materials, transportation, ventilation and management is easily calculated, but the item of labor is more difficult to determine. It varies with the width and depth of the pay gravel, with the number of Chinese employed, with the unevenness of the bedrock, with amount of work in erecting new buildings and making other improvements, and with the labor required to protect the company's property in times of heavy snows and freshets.

The results of a number of figures give the following averages: Average number of men employed daily, 58.5 (22 whites and 38.5 Chinese). Average cost of labor per man, \$2.23. Average number of carloads extracted, per day's labor, 1.87.

This estimate includes all hands employed on the works, underground and on the surface.

A man breasting gravel will take out from 2.80 to 3 carloads a day, and sometimes a little more. This also depends on the depth and compactness of the gravel. As many as 220 carloads have been taken out in one day by the above-cited force.

The pay roll for six months, omitting the labor already cited under the headings "Ventilation" and "Transportation," shows an average of \$3169.75 per month. This gives for 3064 carloads extracted a labor expense of \$1.03 per carload.

COST OF MATERIALS

Of which only yearly inventories are taken (for the year 1892):

Timbers.....	\$931 87
Lumber.....	300 00
Hardware.....	585 18
Rails.....	391 90
Air pipe.....	342 00
Car wheels, etc.....	241 00
Sundries.....	120 93
Freight.....	575 47
Total.....	\$3,488 35
On hand (estimate).....	656 28

\$2,832 07

For one month.....\$236 00

MATERIALS USED IN ONE MONTH,

With an average extraction of 3064 carloads:

1191 pounds powder, No. 2, at 10 cents (average of 6 mos.).....	\$119 10
4800 feet fuse at \$6 per M.....	28 80
1766 caps at \$5 per M.....	8 83
615 pounds candles at 10½ cents.....	64 57
11 gallons coal oil at 26 cents.....	2 86
5 " engine oil at 65 cents.....	3 25
1½ " cylinder oil at 90 cents.....	1 35
6 " lard oil at 90 cents.....	5 40
11 " car oil at 35 cents.....	3 85
131 bushels charcoal at 20 cents.....	26 20
3662 pounds hay at \$25 per ton.....	45 77
1669 pounds barley at \$1.80 per hundred.....	30 04
33 cords of wood at \$2.87.....	94 71
Timbers, lumber, hardware, air pipe, rails, car wheels, sundries, freight, cited in the above yearly inventory.....	236 00

Total.....\$670 73

This gives, after deducting materials already entered in estimates of "Transportation" and "Ventilation," \$443.41, or 14½ cents per carload.

COST OF MANAGEMENT.

The monthly cost of management, including superintendent's salary, office expenses, traveling expenses, cablegrams, expressage on gold, taxes, etc., average of six months, \$649 or 19½ cents per carload. Total expense per carload is therefore as follows:

Ventilation.....	\$0 11
Transportation.....	16
Labor.....	1 03
Materials, etc.....	14½
Management.....	19½

Total.....\$1 64

PRODUCTION.

The total production during five years, from January 1st, 1888, to December 31, 1892, was 140,345 carloads, yielding \$308,245.40, or \$2.20 per carload. The total production of the mine has been \$363,473.60 from 5073 running feet of channel, or \$71.65 per running foot.

WASHING THE GRAVEL.

The dump house, in which the gravel is washed, has a floor 31 feet below the car track. This floor slopes from the two sides toward the center, which is provided with a sluice box 16 inches wide in the bottom, and having a grade of 15 inches to 12 feet. The gravel is dumped on to this floor and washed with the stream from a three-inch nozzle under 25 feet pressure.

The line of sluices, drops, etc., is as follows (beginning at the washing floor): 157 feet sluice boxes, vertical fall or drop, 30 feet; 11 feet ground sluice, 36 feet sluice boxes, 10 feet drop; 24 feet ground sluice, 182 feet sluice boxes. After this the gravel washes down a steep canyon with several falls and short sluices for a distance of 1500 feet, then passes through a double flume and over an under current.

The upper sluice is nominally divided into sections, the upper 59 feet being called the "Upper Sluice," and the lower 98 feet the "Lower Sluice." The next two sluices of 36 and 182 feet are called the "Canyon Sluices," and everything below them is credited to the "Tailings."

In the "Upper Sluice" no quicksilver is used, and it is

*The accompanying paper, of which an abstract was printed in the Press on Jan. 13, 1894, is a most important contribution to literature on the subject of drift mining. In response to numerous inquiries, and by permission of the Technical Society of the Pacific Coast (before which the paper was read), the full text is given.

How to Live Cheaply.

The Scientific Aspect of the Food Question.

We give below some reading especially pertinent to hard times. It not only gives information as to the nutritive value of various human foods, but presents very interesting economic information as to the cost of food. The statement is condensed from a paper by Prof. Charles D. Woods of the Storrs Agricultural Experiment Station in the Report of the New Jersey State Board of Agriculture:

The eating of food is a simple matter, but the ways in which its different constituents are utilized in maintenance of life are far from simple. Our bodies and the food we eat are composed of the same chemical elements, and the compounds of these elements in food are quite similar to those which make up the body. * * * The way of finding out how food is used consists in the comparison of the income with the outgo of the body. The body creates nothing for itself, either of material or energy. All must come to it from without. * * * The science of nutrition, as it is understood to-day, is a matter of definite quantities of income and expenditure, measured in terms of chemical compounds, and of heat and mechanical energy.

The chief two uses of food of animals are: First, to form the materials of the body and make up its wastes; and second, to yield energy in the form of heat to keep the body warm, and muscular and other power for the work it has to do. In forming the tissues and fluids of the body the food serves for building and repair. In yielding energy it serves as fuel.

The different nutrients of food act in different ways in fulfilling these purposes. The principal tissue formers are the protein compounds. These form the framework of the body. They build up and repair the nitrogenous materials, as the muscle and bone, and supply the albuminoids of blood, milk and other fluids. The chief fuel ingredients of food are the carbohydrates and fats. These are either consumed in the body or are stored as fat to be used as occasion demands. In being used as fuel the nutrients of the food tend to protect each other and the materials of the body from being consumed.

Heat and muscular power, like mechanical power, light and electricity, are forms of energy. The energy is latent in the food and is developed as the food is consumed in the body. * * * The value of food for fuel is expressed in terms of potential energy. The quantities of potential energy in food are determined by experiments with an apparatus called a calorimeter. The unit commonly used is the *calorie*, the amount of heat which would raise the temperature of a kilogram of water one degree centigrade (or a pound of water four degrees Fahrenheit).

Taking ordinary food materials as they come, the following general estimate has been made for the average amount of energy in one hundredth of a pound of each of the classes of nutrients:

In 0.01 pound protein.....	18.6 calories.
In 0.01 pound fat.....	42.2 "
In 0.01 pound carbohydrates.....	18.6 "

[Printed tables were distributed showing proportions of each of the three constituents in one pound of various kinds of foods.] The composition of cooked canned corned beef is of considerable importance. Its high content both of proteins and fats is due to the loss of water that comes from the process of cooking and preparation. It furnishes pound for pound more protein than the other specimens of beef, and nearly equals the highest of them in its potential energy. From personal observation also of the methods of its manufacture, I can recommend it as one of the most excellent and economical of foods.

The vegetable foods differ very materially from the animal foods in both composition and digestibility. For the most part they are not as completely digested, and more energy is used up in the assimilation of the digested portions than is the case with animal foods. So that in general a given weight of protein or fat from a vegetable food will not furnish as much material for the use of the body as the same weight from animal sources. * * * Beans are very rich in protein, and on this account are very valuable food. Corn meal differs from wheat flour in having more fat and less protein and carbohydrates. The total energy (food value) of these two foods is nearly the same.

In being consumed in the body to furnish heat and muscular energy the nutrients replace one another in proportion to their potential energy. * * * It has been estimated that a man, to keep his body well nourished, requires about 0.28 lb. of protein and sufficient quantities of fat and carbohydrates to furnish, together with that of the protein, about 3550 calories of potential energy. He would also need a certain amount of mineral matters and water. Sufficient nutrients to furnish that amount of potential energy would be contained in the following food materials, which would therefore suffice for a day's nourishment:

FOOD MATERIALS WHICH WOULD FURNISH NUTRIENTS FOR ONE DAY FOR A MAN AT MODERATE WORK.

KINDS OF FOOD.	Total Food Material, lb.....	Nutrients.				Calories of Potential Energy.....
		Protein, lb.....	Fat, lb.....	Carbohydrates, lb.....	Water, lb.....	
Beefsteak.....	.70	.124	.101			600
Wheat bread.....	1.40	.123	.024	.788		1,790
Potatoes.....	1.60	.031		.243		510
Butter.....	.18		.153			650
Total.....	3.88	.278	.278	1.031		3,550

These materials are daily expended in building up tissues, etc., and since the tissues are made up of the food, practically all the digested protein, fats and carbohydrates leave the body finally as urea, carbonic acid and water. The daily income and expenditure of the human body may be balanced in this way:

ESTIMATED DAILY INCOME AND EXPENDITURE OF THE BODY OF A MAN AT MODERATE WORK

Income—		Outgo—	
	Lbs.		Lbs.
Protein.....	0.28	Urea.....	0.10
Fats.....	0.28	Carbonic acid.....	2.67
Carbohydrates.....	0.99	Water.....	5.40
Mineral matters.....	0.06	Mineral matter (digested).....	0.04
Water of food and drink.....	4.40	Undigested matter.....	0.09
Oxygen.....	2.30		
Total.....	8.30	Total.....	8.30

The cost of food is the principal item of the living expenses of the people—of all, indeed, but the especially well-to-do. In the Report of the Bureau of Statistics of Labor of Massachusetts for 1884 there is summarized the results of investigations into the cost of living of people with different incomes. In Massachusetts, in Great Britain and in Germany, dividing expenses into those for food, clothing, rent, fuel and sundries, the percentage of the whole income expended for food is as follows:

	Annual Income.	Per Cent for Food.
Families in Germany—		
Workingmen.....	\$225 to \$300	62
Intermediate class.....	450 to 600	55
In easy circumstances.....	750 to 1,100	50
Great Britain—		
Workingmen.....	600	51
Massachusetts—		
Workingmen.....	350 to 400	64
".....	450 to 600	63
".....	600 to 750	60
".....	700 to 1,200	56
".....	Above 1,200	51

Although the cost of food is so great, and although the health and strength of all are so intimately connected with and dependent upon their diet, yet even the most intelligent people know less of the actual uses and values of their food for fulfilling its purposes than of almost any other of the necessities of life. People are afraid to economize in food, and will pay higher prices for a less nutritious article. The best food in the sense of that which is the finest in appearance and flavor, and which is sold at the highest price, is not generally the cheapest or the most economical, nor is it always the most healthful.

The New York *Tribune* coal and food fund have sent to many poor families in New York the following supplies, for which they paid one dollar:

KINDS OF FOOD.	Weight, lbs.....	Nutrients.				Calories of Potential Energy.....
		Protein, lb.....	Fat, lb.....	Carbohydrates, lb.....	Water, lb.....	
Hominy.....	5.0	0.400	0.190	8.580		8,225
Oatmeal.....	2.0	0.294	0.142	1.368		3,690
Cornmeal.....	5.0	0.450	0.190	3.530		8,225
Rice.....	2.0	0.148	0.008	1.588		3,260
Codfish (salt).....	2.0	0.312	0.004			410
Salt pork.....	8.0	1.848	0.160	4.796		12,920
Salt.....	2.0	0.018	1.666			7,010
Tea.....	0.5					
Totals.....	26.6	3.430	2.360	14.752		43,740

The above would furnish enough nutrients for a man at moderate work for 12 days. * * We waste at the store, at the market and in the house enough to make us wealthy if we would only save. The fathers and mothers do not understand the little arts of economy and the sons and daughters do not learn them, and we are somewhat inclined to think it beneath our dignity as free-born and well-to-do American citizens to devote our attention to them. We endeavor to make our diet suit our palate by paying high prices in the market rather than by skillfully cooking and tastefully serving at home. We buy more than we need; and, what makes the matter worse, it is frequently those who most need to save that are most wasteful.

The remedy for the evil, so far as it applies to the chief item of our living expenses—our food—must be sought in two ways—in an understanding of the elementary facts regarding food and nutrition and the acceptance of the doctrine that economy is not only respectable, but honorable. And it was in the hope of helping to a better understanding of the subject of nutrition and to show how some of the principal facts may be put to practical application that I prepared this paper.

The Sutro Tunnel Troubles.

By the recent decision of Judge Hawley of the United States Circuit Court for Nevada, the long litigation growing out of the reorganization of the old Sutro Tunnel Company has been ended and the plans of the reorganizers have been upheld. By the decision the complainants get nothing, while the defendants are dismissed with their costs.

The record of the transactions which led to the litigation is an interesting chapter in the mining history of California and Nevada. Along in 1865 and 1866 Adolph Sutro of this city secured from the State of Nevada and from the United States a right of way and authorization for the construction of a mining, draining and exploring tunnel to the Comstock lode, in the State of Nevada. In November, 1869, the Sutro Tunnel Company, a corporation for the purpose of carrying on this work, was formed with a capital stock of \$20,000,000, divided into 2,000,000 shares of \$10. All of the stock was disposed of, and in earlier years it was by no means a drug on the market.

In January, 1877, the company executed a mortgage to Hugh McCalmont and others, all Scottish capitalists. This mortgage was increased by further advances and by accrued interest, until, in 1886, there was \$1,600,000 due on the mortgage, and steps were taken to foreclose the same, William Johns being appointed receiver.

While the suit in foreclosure was in progress some of the shareholders, seeking to avoid a foreclosure wherein all would be lost, began overtures through Theodore Sutro of New York for a settlement of the mortgage. An offer was finally received from the McCalmonts agreeing to take \$800,000 for their mortgage on January 1, 1888. Notices were sent out to all stockholders asking that 50 cents per share be sent in to pay off the mortgage. Some responded, but when the time arrived which was fixed in the offer not half of the \$800,000 had been secured. A syndicate was formed in New York and an extension of time secured from the Scotch capitalists. Other notices were sent out and more money received. About \$550,000 was collected from the stockholders. The syndicate put up the required \$250,000 additional, and the mortgage was purchased in the name of the Union Trust Company of New York.

Other notices were sent to the stockholders and all were allowed to come into the company who desired to do so. About four-fifths of the stock came in. The Comstock Tunnel Company was then formed, and the property transferred to it by the Union Trust Company. Stock in the new company was issued to the holders of the old stock who had come into the reorganization scheme and helped to pay the mortgage, share for share.

Of those who remained outside were Joseph Aron of Paris, a member of the London, Paris and American Banking Company, and Frank J. Symmes of Thomas Day & Co. The former owned about 90,000 shares and had gone into the reorganization with about 50,000 shares; the latter owned about 90,000 shares and was in on the new deal with 40,000 shares.

In December, 1889, the suit just decided was begun by Mr. Symmes and others to set aside all previous transactions on the ground of fraud alleged to have been committed by the defendants, who were, besides the Union Trust Company, the Sutro Tunnel Company, the Comstock Tunnel Company, and the members of the New York syndicate heretofore referred to. Testimony was taken in New York and San Francisco. The bulk of testimony was submitted to the court at Carson, Nev., in February, 1893. At the time arguments were made by H. E. Houghton and R. L. Gear for the complainants and by W. M. Pierson and Edmund Tausky for the defense. The argument lasted eleven days, and at its close the Court took the case under advisement.

For 13 months a decision was awaited. It was rendered on the 5th inst. By it the defense was upheld in all its points, one of which was that the complainants having come into the reorganization scheme with part of the stock they represented, could not afterward cry fraud.

THE Redding *Free Press* combats the prevalent opinion that the surface placers have been cleaned up throughout California. It says the worn-out placers of Shasta and neighboring mining counties will afford a living to many men. Especially in the rainy season is this so. He is a poor man, indeed, who cannot make a dollar or a half-dollar with pan, pick and rocker, and a man in the mines can live on \$15 per month. Last week an old pioneer miner picked up a nugget weighing \$515 or more, and nuggets of greater or less value will be discovered, to say nothing of the fine gold, from time to time, as long as Shasta county exists. Even now many old miners, too feeble to do a week's actual work in a month, are making a living from our placers, and a young man with push, who is not afraid to work, could do much better.

Scientific Progress.

Edison's Kinetograph.

A press dispatch from New York says that Thomas A. Edison has consented to tell exactly what he has accomplished in reproducing the motions of an object by photography. This is the first direct announcement that the kinetograph, as the new photographic apparatus is called, has proven successful.

Everybody has seen nickel-in-the-slot machines which contain phonographs and play any kind of a tune previously sung into them. Mr. Edison has now ready for the market a similar machine containing his moving pictures, which are set agoing when a nickel is put into the slot. This machine he calls a kinetoscope. The kinetograph is the machine which takes photographs, and the kinetoscope the machine which displays them to the eye.

The kinetoscope shown by Mr. Edison in his workshop contains a picture of a five-cent harper shop. The Lilliputian figures of course portray the actions of a scene taken from life. Mr. Edison said:

"Some time ago it occurred to me that it might be possible to invent something that would do for the eye what the phonograph does for the ear, an instrument in fact that would faithfully record and reproduce practically all motions. I was familiar with the zoetrope, an instrument on which certain pictures were painted and which seemed to give the figures a sort of motion, and I was also very much interested in the experiments of Maybridge, who photographed horses in motion by instantaneous photography and reproduced the movements. But all these were very crude and resulted in jerky motions. The eyes are too quick for such photographs.

"I saw that to produce pure motion pictures must be taken with sufficient rapidity to record movements of less than an inch in any part of the body, a longer movement than that producing a jar which destroyed the illusion. Then began a series of experiments in photographing moving objects, and we got our apparatus to take twenty-five different photographs in a second. But this was not sufficient. I found that the human retina was capable of taking about forty-five or forty-six photographs and communicating them to the brain. The difficulty was to give sufficient exposure even for the instantaneous photographic apparatus.

"I found that if a plate were exposed a sixtieth part of a second to a scene that was very light, with a very dark background, a perfect photograph resulted. It was but a simple process then to figure out how fast a machine would have to run between exposures to give forty-six pictures each a sixtieth part of a second exposure. I figured that it would have to move from one exposure to another in 1-185th of a second. That is to say, the instrument must be standing still for exposure three-fourths of the second and must be racing along at an enormous rate of speed the rest of the second so as to get the whole forty-six plates properly placed for exposure.

"If one picture is a thousandth part of an inch out of the exact lines of the preceding picture the sensitive eye instantly notices a tremor of the picture which instantly destroys the illusion. The various devices for properly displaying moving scenes are of secondary importance.

"This has been largely a work of sentiment on my part. I do not believe there is much money in it, but I believe it is of interest to science and history. A great man will never die if his pictures and speeches are saved by the kinetograph and phonograph."

The average weight of 20,000 men and women weighed at Boston was: Men, 141½ pounds; women, 124½ pounds.

The Discovery of the Glacial Epoch.

It is a little more than 50 years ago that one of the most potent agents in modifying the surface features of our country was first recognized. Before 1840, when Agassiz accompanied Buckland to Scotland, the Lake district and Wales, discovering everywhere the same indications of the former presence of glaciers as they are to be found so abundantly in Switzerland, no geologist had conceived the possibility of a recent glacial epoch in the temperate portion of the northern hemisphere. From that year, however, a new science came into existence, and it was recognized that only by a careful study of existing glaciers, of the nature of the work they now do, and of the indications of the work they have done in past ages, could we explain many curious phenomena that had hitherto been vaguely regarded as indications of diluvial agency.

One of the first fruits of the new science was the conversion of the author of Reliquiæ Diluvianæ—Dr. Buckland—who, having studied the work of glaciers in Switzerland in company with Agassiz, became convinced that numerous phenomena he had observed in this country could only be due to the very same causes. In November, 1840, he read a paper before the Geological Society on the Evidences of Glaciers in Scotland and the North of England, and from that time to the present the study of glaciers and of their work has been systematically pursued with a large amount of success.—From the Ice Age and Its Work, by Alfred R. Wallace, in Popular Science Monthly for March.

Epilepsy and Errors of Refraction.

Mr. Work Dodd has discovered a strange relation between errors of refraction and epilepsy. The former, given a certain condition of instability of the nervous system, may excite the latter. In other words, the relation that errors of refraction and epilepsy hold toward each other is that of cause and effect. This is a most useful argument to be used in most cases where people are either too thoughtless or too indolent to have their visual refraction corrected when necessary. Mr. Dodd points out, in addition to the foregoing, that the correction of the errors of refraction will, in combination with other treatment, in many cases cure or relieve the epileptic condition, and that, although in some cases, when the refraction error has been corrected, the epilepsy will continue, it will only be in a modified form, in consequence of other irritation, even though the error of refraction may have been the exciting cause of the fits in the first instance. Mr. Dodd is strongly of opinion that in every case of epilepsy the eyes should be carefully examined, with a view of correcting any error of refraction that may exist by the use of proper spectacles.

Carbonic Acid in Air.

A paper on the value of determinations of the proportion of carbonic acid in air as a measure of the efficiency of ventilation has been contributed to the Journal of the American Chemical Society by Mr. E. H. Richards, who states that for the past nine years the Laboratory of Sanitary Chemistry at the Massachusetts Institute of Technology has had exceptional opportunities for investigating this subject, because the Walker building is mechanically ventilated under the direction of an expert, and is fully controlled by the engineer, who has records for all these years of the quantity and temperature of the air supplied to each room, and of the temperature of these rooms taken four times every day. During these nine years some 5000 determinations of the carbonic acid have been made in these rooms by 200 students. Many problems arising out of these circumstances have been studied and reported upon, but the net gain of knowledge appears to be meager. The outer air surrounding the Institute shows an ordinary

proportion of from 3.7 to 4.2 parts of carbonic acid in 10,000 parts of air. The air in the empty rooms shows a rise of carbonic acid of about 0.5 part, due to decomposition of the organic matter present in the flues, the floors and the walls. The air of the building in general, of the halls, reading rooms, etc., which are open, and in which people are constantly moving about, is maintained at about five parts as an average of all tests for eight years. The air of most of the lecture rooms has contained from 6 to 8 parts, rising to 10 or 12 parts for the large and more crowded rooms, according to the state of the weather outside. From this experience it would appear that students can work well in a clean room with about seven parts in 10,000 of carbonic acid. Much more than this causes dullness, and anything over 13 parts is an almost insuperable obstacle to the full acquisition of knowledge by the classes.

The cave animals of North America, according to Prof. A. S. Packard of Brown University, comprise 172 species of blind creatures, nearly all of which are mostly white in color.

PIONEER REDUCTION CO., NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract, or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ores or concentrates.

Addressee all communications to

Rates of Tuition Very Moderate.

Bookkeeping, Penmanship, Shorthand, Typewriting, English Branches, etc. Graduates aided in getting positions. Send for circulars. T. A. ROBINSON, Pres.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, Jr.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by Dewey Publishing Co., 220 Market St., San Francisco, Cal.

Mechanical Progress.

New System for Flying Machine.

At a meeting of the Austrian Society of Engineers and Architects, held November 18, 1893, Prof. George Wellner, of the Technical High School at Brünn, laid before a crowded and enthusiastic audience the first publication of his proposed system of aerial navigation—a system which he claims to be absolutely new, says the *Engineering Magazine*. The principle which Prof. Wellner proposes to employ is perhaps most briefly expressed in the magnificent compound name which he himself has conferred upon the proposed machine—"Segel-radflug-maschine"—which in English we can hardly render more concisely than by the expression "flying machine with paddle-wheel sails." To use the inventor's words, his machine is neither more nor less than a mechanical reproduction of the mechanism of a bird's wing, albeit the professor claims, in some respects, to imitate rather the insect than the bird, and especially in this, that many insects can and do readily remain fixed in a given position in the air, whereas birds can accomplish this only by an excessive expenditure of work.

Prof. Wellner raises and propels his flying-machine by means of the rotation of large wheels. The axes of these wheels, like those of screw propellers, are either coincident or parallel with that of the vessel and the direction of its forward motion, and in the matter of propulsion the action of the wheels is similar to that of a propeller; but in respect to the raising of a machine and keeping it suspended in the air, they differ radically in their action from the screw, and resemble rather the paddle-wheel, with movable floats, for here the floats are so arranged, by means of eccentrics and eccentric rods, that when at the uppermost and lowermost points of a revolution they are so inclined that the vertical component of their pressure forces the air downward and the machine upward (*vice versa*, of course, when their action is reversed); and when their arms are in the horizontal position, the floats exert no tendency to raise or lower the machine. Propulsion is provided for by so inclining the webs used for bracing the floats that they act as elements in the blade of a screw, and thus drive the machine forward.

Drawings were presented, showing a "twin-screw" application of the device. A machine designed to carry from four to eight persons has two wheels (or more properly cylinders) 21 feet in diameter and 63 feet long, and between and below these is suspended a cigar-shaped car 8 feet in diameter and 40 feet long, carrying the motors, the passengers, etc. Each wheel or cylinder has arms or spokes, arranged in eight radial planes and carrying as many floats. The arms, like the axles, are of steel tubing. Steering is accomplished by means of four rudders, which, by being placed at right angles to the path of the vessel, may, the inventor claims, be used to hold the machine steady, without motion forward or backward.

Such a machine, at 135 revolutions per minute, would exert 30 horse power, would lift 14,000 pounds and would be capable of traveling from 45 to 90 miles per hour. A machine for two persons would require from 30 to 40 horse power and would cost from \$8,000 to \$12,000.

A small model, with but one wheel and worked by hand, was exhibited, and was run backward so as to exert a downward pressure in addition to its weight, and this pressure was measured by weighing it upon a scale. The current of air through the machine, downward when the machine was run in the normal direction, and *vice versa*, was illustrated by the convenient means of tobacco smoke.

So enthusiastic were the members present that a resolution was unanimously adopted,

requesting the board of directors to suggest ways and means for carrying on these experiments; and at the meeting of December 30th it was announced that a fund of \$800 had been subscribed and placed at the disposal of a committee appointed to prosecute the work.

The inventor says "these are not empty phantoms—not hazy picturings of the desires or airy machinations—that I am pursuing. I stand upon solid ground. I move forward, step by step, upon a mechanically constructive basis. My whole nature revolts from the fantastic."

The Sand Blast in Glass Making.

It is stated that the sand blast was first used in the glass trade about 20 years ago by Mr. Tilghman, an engineer of Philadelphia, who observed that the surface of glass exposed to a stream of sand thrown against it by an air current in a few minutes becomes perfectly dull. He at once constructed a rotating bellows for producing the air current, which was conducted through a perpendicular tube, at the upper end of which the sand was brought into contact with the current. The glass was held over the mouth of the tube at a distance of about an inch, and not more than 20 or 30 seconds were required to dull the surface. In cases where designs or ornamentations had been put on the glass with some elastic substance, as rubber, thick oil paint or papier mache, the sand attacked only the uncovered portions, so that it became possible to produce dull ornaments on a bright background, or vice versa.

Tilghman had his invention patented, and since the expiration of his patent the sand-blowing machine has undergone considerable improvements, and is now constructed in different sizes to accommodate any class of customers. Sand-blowing machines are used principally for dulling and ornamenting all kinds of hollow and plate glass; also for polishing metal castings and cleaning plates, previous to gilding or silvering them, and for engraving wood, metal or stone. The simplest way of protecting that portion of the surface to remain untouched by the sand is to cut the designs out of strong paper and paste them on with glue, which, however, must be carefully done to avoid the formation of blasts. A more rational method is to cut the patterns out of sheet metal, which is especially advisable by plate glass. This method possesses the further advantage that such designs may be used repeatedly, for which purpose they should be covered with a protecting coat, for instance of oil paint, which must be renewed several times.

Heating with Exhaust Steam.

The economy of using exhaust steam to heat offices and factories and to warm drying apparatus in paper mills and elsewhere, has long been recognized; but it is not yet understood as fully as might be that even with exhaust steam there is apt to be a considerable loss through "hack pressure." It is easy to see, for instance, that if a boiler carries 80 pounds of steam, and the cylinder pressure is 40, and it takes five pounds to overcome the resistance offered by the pipes of the heating system, one-eighth of the effective force of the plant is wasted, and this is equivalent to throwing away so much coal, says the *New York Tribune*.

To overcome the back pressure, and hence to reduce the cost of heating and drying, Andrew G. Paul, of Boston, some time ago invented and patented the idea of exhausting the air from the circulatory system. The special device which he has begun to introduce is an ejector, but his claims cover any other method of creating a vacuum independently. The idea is attracting a good deal of attention in New England and elsewhere.

In 1890 the railroads of the world were estimated at 370,281 miles.

ASSAYING AND ANALYSIS.

"Consulting Associate Mining Attorney at Law."

Will examine and report upon "Title and Exact Value" of GOLD, SILVER, LEAD, COPPER, COAL, IRON, CLAY or other MINERAL PROPERTIES in any part of the world. Any information mining men may desire to know, relative to the mineral or coal resources of the entire Pacific Northwest, will be honestly given.

DR. WILLIS E. EVERETTE, 1818 E. ST.,
Tacoma, State of Washington, U. S. A.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$5.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formula as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is prepared that it is useful to uneducated men as well as scientists.

The Twenty-Seventh Edition of a Deservedly Popular Technical Book, *The Painter, Gilder and Varnisher's Companion*. Revised, Enlarged and Improved.

JUST READY.

Price, \$1.50.

Free of Postage to any Address in the World.

THE PAINTER, GILDER AND VARNISHER'S COMPANION.

Comprising the Manufacture and Test of Pigments, the Arts of Painting, Graining, Marbling, Staining, Sign-Writing, Varnishing, Glass-Staining, and Gilding on Glass; together with Coach Painting and Varnishing, and the Principles of the Harmony and Contrast of Colors. Twenty-seventh edition. Revised, Enlarged and in great part rewritten. By William T. Brandt, Editor of "Varnishes, Lacquers, Printing Inks, and Sealing Waxes." Illustrated. In one volume, 12mo, 416 pages, bound in cloth.

Price \$1.50, free of postage to any address in the world.

A circular of 20 pages, showing the full Table of Contents of this Useful and Popular Book, will be sent free of postage to any one in any part of the world who will furnish his address.

GAS WORK A SPECIALTY.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstract calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical minor or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:
General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formula and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Minors' Inlets; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend-Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimation, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

Useful Information.

Spectacles and Eyesight.

The proportion of people who wear spectacles is constantly increasing. Is this a thing to be lamented? In other words, does it indicate a deterioration of eyesight under modern conditions of life? Those who may be supposed to be best qualified to answer these questions answer them without hesitation in the negative. More spectacles are worn, not because poor vision is more common, but because the eye has been more intelligently studied.

A recent writer in the *Atlantic Monthly* says it is the exception to find persons whose eyes are normal and perfect. At an annual meeting of the British Medical Association, not long ago, the president of the ophthalmological section expressed the hope that the time will come when "a man who goes about with his eyes naked will be so rare that the sight of him will almost raise a blush."

This is as much as to say that since almost every man's sight needs correction, it will be a sign of advancing knowledge when almost every man wears spectacles. Of the advance already made in this direction the *Atlantic Monthly* writer says:

"The methods of testing the defects of vision have, in the last two decades, been brought to a standard of accuracy and refinement previously unknown. Thus many troubles, disabilities and maladies hitherto suffered in patience, or treated incorrectly and in vain, are now traced to defects of vision, and are quickly remedied by the use of appropriate glasses, concave, convex, cylindrical or prismatic.

"The schoolboy's headache, the seamstress's browache, the convergent squint of childhood, so far as they are the results of faulty refraction, are beginning to be erased from the catalogue of human woes."

Some specialists go so far as to maintain that every child should have his vision tested by a competent oculist. "It is far better," says the *Atlantic* writer already quoted, "to discover visual defects and to remedy them at the beginning of school life than to have the child sent home after his sight has been seriously injured, as dull of vision, or unable to get through his studies, and the subject of periodical 'hilarious headaches'—matters nowadays of constant occurrence."—*Yonth's Companion*.

How to Sleep Well.

In sleeping much depends on securing a comfortable position. Lying on the back would seem to give the most ease, but general experience and practice prove that it does not, and it is liable to some definite objections, says a writer in the *Jenness Miller Monthly*. In a weakly state of the heart and blood vessels, and in certain morbid conditions of the brain, the blood seems to gravitate to the back of the head, and to produce troublesome dreams. Persons who have contracted chests, and who have had plenrisy and retain adhesions of the lungs, do not sleep well on the back. Nearly all who are inclined to snore do so in that position.

For these and other reasons it is, therefore, better to lie on the side, and in lung disease to lie on the weak side, so as to leave the healthy lung free to expand. It is well to choose the right side, because, when the body is thus placed, the food gravitates more easily out of the stomach into the intestines.

Sleeping with the arm thrown over the head is to be deprecated; but this position is often assumed during sleep, because circulation is then free in the extremities and the head and neck, and the muscles in the chest are drawn up and fixed by the shoulders, and thus expansion of the thorax is easy. The chief objections to this position are that it creates a tendency to cramp and cold in

the arms, and sometimes seems to cause headaches and dreams.

The best sleep is obtained when the shutters are closed so as to make the room dark, and the windows are adjusted so as to admit plenty of fresh air. Early rising is not a virtue unless the riser has secured sleep enough, and the best rising is obtained when the sleeper wakes naturally.

Increasing the Height of a Chimney While in Use.

A remarkable feat has been recently accomplished at the Bonsecours Spinning Works at Nancy, says *Industries and Iron*, namely, increasing the height of a chimney about 100 feet high by about 30 feet, without stopping the works for a single day. Owing to the power being increased, the existing chimney did not give sufficient draft for the increased number of boilers, and one or two alterations had to be faced—either to build a new chimney alongside the old one, or to increase the height of the latter. Augustus Bartling of Bernburg, Anhalt, offered to increase the height of the old chimney without interfering with the work of the mills. Aided by another man, whose agility and nerve were equal to his own, Mr. Bartling fixed a series of light steel ladders to the chimney by means of iron hooks driven in between the courses of the bricks, erected a pulley at the top of the chimney and a flight of scaffolding all around, and then having lowered the cornice surmounting the chimney, they built on to the top at the rate of about four to five feet per day. The whole work occupied eight days, and was perfectly successful. While this is the first chimney dealt with in this manner in France, Mr. Bartling states that he has carried out similar operations in Germany.

Testing Lubricating Oil.

For testing the viscosity of lubricating oil, the following apparatus is in use on the Philadelphia & Reading railroad: A cylinder $2\frac{1}{2}$ inches long is suspended in the oil to be tested, by means of a fine steel wire attached to its upper end to a knob inserted in a stiff frame. By twisting this knob the middle of its length the wire has attached to it a horizontal disc, graduated in degrees, which rotates with the wire when the latter is turned, and serves to measure the angles of the oscillation. In making a test the oil is surrounded by a bath of water or paraffine to bring it to the required temperature. The disc on the wire is clamped, and the knob at the top turned through an angle of 360 degrees. The clamp holding the disc is then released, and the torsion in the wire causes the cylinder immersed in the oil to move through angles which become less at each succeeding oscillation. These angles are measured by the disc, and form a criterion of the viscosity of the oil.

Durol.

"Durol," the new hardening composition for steel, has, we are informed, says *Invention* of London, been tested and approved by the largest iron works, steel manufacturers, mechanical engineers, etc., on the continent, and most astonishing results have, it is said, been obtained, whereby "Durol" has been pronounced to stand quite alone amongst all "hardeners." "Durol" is, accordingly, of great importance to the steel industry. Steel manufactured with "Durol" obtains, we are told, the hardness of a diamond whilst retaining its tenacity and temper.

Overcoming Quicksand.

In some recent sewerage work at Boston the foundation for a length of brick sewer proved to be a quicksand, which boiled up into the trench when it was attempted to excavate it. The difficulty was overcome by driving a line of tube wells along the side

of the trench into the quicksand at a distance of about eight feet apart. On connecting these wells with a pump, it was found possible to bring the water under control, and to drain the sand through which the excavation had to be made.

A splendid record for safety of ships and cargoes was made during 1893 by the large fleet of grain carriers between Pacific ports and Europe. The voyage is the longest and stormiest of all routes in the world's commerce, yet out of 326 vessels which sailed from San Francisco and other Pacific ports for Europe, only one failed to arrive at her destination safely and with cargo in good order. This one ship was stranded on a South Pacific island, and lack of wrecking facilities alone prevented her getting off and resuming her voyage. Her crew was saved.

Electricity.

To Prevent Collisions.

A Cincinnati inventor, Dr. Von Dolcke, has devised a plan for the prevention of collisions on railroads in which electric storage batteries play the principal part, says *Electricity*. The complete details have not yet been published, as the patents for the device have not been secured yet, but an outline of the plan is as follows: The entire road is to be divided into sections of 500 feet to a half mile each. Wires are to be connected with the flange of the rail at certain points from telegraph poles that stand along the road. In this way the inventor proposes that every road that wants to prevent collisions shall fix their tracks. Every engine on the road is to be provided with a storage battery. When one engine is on the track the circuit is open, but if a following or approaching train comes within the 500 feet or half mile section, the circuit for each battery is closed, and the result is that a torpedo on each cab explodes and warns the engineer of danger. If by any chance the engineer is sleepy and does not hear the discharge, the battery, in a limited time, works a wire that reverses the lever and stops the train. As an earnest of what the invention will do, it is proposed to start two engines headed toward each other, and let them try to approach. Dr. Von Dolcke says they will come to a standstill before any damage is done. He says experienced railroad men have told him that a train going 40 miles an hour can be stopped in 300 feet, and he proposes to be safe and put the limit at 500 or perhaps a half mile. Some of the details of his invention the doctor would not give out, but he says he will explain everything when his papers arrive.

Dress Ruined by Electricity.

It is not often that you hear of a dress being ruined by electricity, yet such an accident really occurred at the Alvin Theater Tuesday night, says a writer in the *Pittsburg Dispatch*. In one act Miss Robinson wears a handsome gown, which is trimmed around the bottom and the waist with a sort of metallic embroidery. On Monday night, when she answered her cue by coming out of the house which is in the setting, she noticed a bright flash of light just as she stepped out of the door before the audience. She thought nothing of it, attributing the flash to the stage hands making some electric connection back in the wings. On Tuesday night, at the same part of the play, Miss Robinson was walking slowly to the door awaiting her cue, when she again saw the flash, and, looking down, found herself enveloped in a ring of fire around the bottom of her skirt. She had no time to call for assistance, but, hearing her cue, stepped upon the stage, delighted to find the fire did not follow her. After the act was over she examined her dress and found that it was ruined, the metallic trimming around the skirt having melted entirely off. The cause

of the strange accident was soon found. The metallic embroidery had come in contact with one of the electric sockets in the floor from which current is obtained to light the bunch lights. A circuit being found, the continuous trimming made a sort of arc. Had there been any metallic connection with the copious trimming of the same kind upon the waist, the accident might have cost the actress her life.

Lighting the Nation's Capitol.

It is probable that the electric-lighting plant to be put in the nation's Capitol will not only be required to light that building, but also to illuminate the Congressional library, which is to be the largest building of its kind in the world, and which, by reason of its uses, will require the best class of illumination.

To accommodate such a plant it will be necessary to locate the engine and dynamos in a structure erected for this special purpose. The location of the power-house is now being carefully considered, and the decision will probably be reached very soon. The house will be ornamental in appearance and will be of sufficient size to contain not only the eight dynamos necessary for the present, but also for other buildings that may be added to the group clustering around the Capitol, notably the home for the Supreme Court.

A careful estimate has placed the original cost of the building, the machinery, the wiring and general installation of the plant at \$200,000. This will insure the work to be of the best character and the plant to be of sufficient size to furnish all the light that can be used in the buildings and the grounds. The latter is a most important item in the calculations, for at present there is an utterly inadequate illumination of the great park. It is not certain whether the grounds will be lighted by arc lamps or groups of incandescent globes. But this is a matter of detail to be settled afterward.

A rough estimate that has already been made of the cost of maintaining the new plant, which will do not only the work now done by the gas and electric plants in the Capitol building, but also the entire work of lighting the new library building and the Malby House, shows that it will cost in the neighborhood of \$19,000.

An Electro-Oxy-Hydrogen Blow-Pipe.

H. N. Warren, in the *Chemical News* for January 19, 1894, describes a new form of oxy-hydrogen blow-pipe in which the gases are obtained directly from the electric decomposition of water. The water is decomposed in a U-tube, as in the familiar laboratory experiment, and the gases rise directly into the blow-pipe, where they mix. Thus the action is perfectly automatic and of almost indefinite duration; no taps are required, the gases are in the exact proportions required by theory, and the flame may be regulated by increasing or decreasing the decomposing electric current.

Cables of the World.

According to latest reports, there are in the world 104,344 miles of sub-marine telegraph cable. Of this total the various governments own 14,480 miles of cable and 21,560 of wire; the balance is owned by private companies. Where the telephone wires are overlaid, the speed of transmission is at the rate of 16,000 miles a second; where the wires are through cables under the sea, the speed is not more than 6020 miles a second.

A French Electric Carriage.

A French carriage which carries six persons is driven by an electric motor receiving current from a battery of 54 Dujardin accumulators, and has a total weight of about a ton and a third. One charge of the accumulators suffices for a trip of 44 miles at a speed of ten miles an hour.

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

41 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents of the **Denver Fire Clay Co.** and for the **Morgan Crucible Co., Battersea, England.** Also for **E. G. Denniston's Silver Plated Amalgam Plates.** The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at the lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifflings also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Ouberging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scourification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Copper Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Hydrostatic Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

CHEMICAL LABORATORY,
524 SACRAMENTO STREET, - - SAN FRANCISCO, CAL.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs in the shaft. Works with 10 per cent less power. First outlay one-third less. Suitable to any underly or downright shaft. Occupies less space in the shaft. Has been tested a year and proved to work satisfactory in every respect. GLAND OF STUFFING-BOX TIGHTENED AND LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING OR BUCKET PUMP.

The valve-clack and bucket can be changed when the pump is under water. Bucket lasts six times as long as a leather geared bucket, often saving expense of putting down another pump, especially in jack-head pumps, where the bucket and clack cannot be changed under water. Special attention is called to this new system of pumping, and also to the self-screwing stuffing-box and new bucket gearing, which are applicable to all kinds of plunger, force, and bucket pumps.

WM. NANCE, Grass Valley, Nevada County, Cal.

THE GRIFFIN MILL.

A perfect pulverizer of all refractory substances by either the wet or dry process. It works better and at less expense than any other Mill, and is conceded to be the only perfect pulverizing Mill Manufactured.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

Closed Down.—*Calaveras Citizen*: On Saturday last the Sheep Ranch mine closed down, after a most unparalleled record of about 25 years. The whistle that has blown the signal of work shifts so faithfully for years blew its last blast, perhaps forever, long, sad and sorrowful, until the steam in the boilers no longer gave detonation through the whistle pipe. The mine that so many years had given life to the town had closed. The occasion was one of the most solemn, and tears came to eyes that told the tale of "be it ever so humble, there is no place like home." The town has as its residents some who have grown from the cradle to manhood and womanhood who will now be cast out from their surroundings to seek for fortune elsewhere on the broad land. Saturday night a ball was given by the people of the town, trying to make merry and while away the solitude that would ever and anon present itself to the grave and thoughtful mind. The attendance was quite large and many grown gray in the village turned out to join in the farewell dance of the dear old town.

Extending Tunnels.—*Amador Ledger*, March 9: At the Albany, the Astoria tunnels leading from the crosscut north and south are being extended on vein matter, the face of same carrying stringers of quartz which give low assays. The Farrell people are still extending their tunnel into the ore body. Their mill is still closed down, but they expect to resume crushing as soon as Messrs. Wise and Seligman return from Oakland.

The nine tributaries who have the Amador Queen No. 2 leased have their ore bin full of ore, and are repairing one battery of the mill and expect to commence crushing in a short time.

The north drift of the 800-foot level in the Hardenburg is being advanced. As the chutes of ore so far encountered are very short, the company is living in hopes that more extensive bodies will be found as they advance north, as there are several hundred feet of virgin ground yet unexplored.

Satter Creek has taken on a busy appearance once more. Both the Wildman mill and the Hector mill have been running for a week or more. About 200 tons of ore were run through the Hector mill by the men who are working the property upon the tribute plan. They stopped Tuesday to make a clean-up, and if the result thereof is satisfactory, will continue to take out quartz.

Five tons of quartz have been shipped to the Midwinter Fair from the Bay State mine and placed on exhibition in the form of a pyramid. A new contract for sinking the shaft 115 feet deeper has been awarded to the same parties, who have just completed the 100-foot contract. This sinking will bring the shaft down to 500 feet with a 40-foot stump. The favorable ground still holds out, and the contractors are making good progress.

Butte.

New Air Compressors.—*Forbestown News*: The new air compressors at the Gold Bank mine have been in working order for the past ten days. Everything about the machinery works to a charm, and two Barleigh drills are driven by it, and more will be placed in operation in the near future. This new machinery will give this mine a chance to keep their development work ahead of their milling capacity.

Calaveras.

Proving Its Richness.—*Prospect*: The old Gold Hill mine at Smith's Flat, which for many years proved a bonanza to its owners, the Osborns, is again proving its richness after some time of unproductiveness. The mine passed into the hands of a Chicago company a few years ago and has been pretty poorly managed by them so far as getting gold out of the ground is concerned. It appears that the company has become much discouraged, and openly charged that the mine had been misrepresented, and even that it had been "salted" for their benefit. Of course the reputation of the mine was too well established here for such charges to have any effect, but it seems that Wm. Osborn recently told the management that if they would let him have charge of the mine for a short time he would prove all that had been claimed for it. He accordingly was put to work, with the result that some time the first of last week he took out \$600 in one day, and on Wednesday of that week \$1500 more. In all, nearly \$3000 was taken out during the week.

El Dorado.

The Stillwagon.—*To the Editor*:—The Stillwagon Mining and Milling Company—a corporation in Sacramento—has bonded the well-known Stillwagon mine, situated about six miles from Grizzly Flats. The company has placed the ditch in first-class repair and has erected a modern five-stamp mill with concentrator; also an air compressor of sufficient capacity to run two power drills. Blacksmith shop and boarding-house all complete are on the property. The lead is small, but the rock is rich. Two tunnels penetrate the mountain from the south side. The ledge is in eight all the way, and varies in thickness from two inches to two feet. The lower tunnel is in about 400 feet, and exposes a chute of ore extending some 50 feet along the vein. The rock is good, the lowest assay being \$125 per ton. At the present writing, two shifts are at work in stoping. A small Rand drill is used. Formation is granite, but the fissure shows no sign of pinching out. It is the purpose of the com-

pany to thoroughly prospect the hill during the present season. An Ingersoll-Sergeant machine will be used in the head of the tunnel. It takes something like 150 inches of water to run the six-foot Knight compressor wheel and 100 inches to run the four-foot mill wheel. The fall of water is 73 feet. The superintendent is W. S. Weymouth, formerly superintendent of the South Cosmopolitan Company; president, Jos. H. Gray; secretary, Geo. C. Holbrook. Sacramento, March 10, 1894. H.

Kern.

Deposits of Colemanite.—*Bakersfield Californian*: Parties prospecting near Colorado camp, in the Red Rock range, have recently found quite extensive deposits of "colemanite" or "cotton balls," and have made quite a number of locations. Not far from this locality Searles Bros. & Killings found some deposits of colemanite several years ago, but they were not extensive and were speedily worked out. Colemanite is a variety of boracic acid and occurs in nodules. Its cottony appearance is due to efflorescence of the outer surface. Combined with two parts of soda ash it makes the borax of commerce, which is a bi-borate of soda.

Nevada.

On a Paying Basis.—*Union*: That the Orleans mine will develop into one of the best paying mines in this district is a certainty. Acting Superintendent Brockington informs the *Union* reporter that five stamps of the Empire mill are constantly working on ore from the Orleans. The rock pays over \$25 a ton, which is very satisfactory indeed. The mine is paying its own way, and should the company feel disposed after this month's clean-up, they could declare a dividend. This will not be done, however, for the reason that the money will be expended in building a five-stamp mill—to which five stamps will be added as soon as they are found necessary. The Powling, or main chute, is now being worked.

Mine Sold.—*Telegraph*: The Normandy mine, owned by Messrs. Senechal and Richards and located on Deadman's Flat, has been sold to the Gold Trust and Development Company of which Dr. Stephen H. Emmens, the eminent chemist and lecturer, is the head. There has been but little work done on the Normandy mine, but there is a good-sized gold-bearing ledge in the shaft, and there has been a great amount of gold taken from the surface surrounding the ledge. The company that has bought the claim has simple means and is going to work it immediately. Mr. Frank DuMaine will have full charge of the affairs at the mine, and he informs us that very extensive hoisting and pumping machinery will be erected just as soon as the lumber and other necessary machinery can be placed on the ground. Mr. DuMaine will give the business his entire attention, and in him the company has secured a faithful and competent man.

Bound to Win.—*Herald*: The San Jose Mining Company will probably have to try another way of getting at their rich gravel deposit on the Washington ridge. They have been working through a vertical shaft about 300 feet deep, and the water comes too fast for them. They are thinking of arranging with the Centennial Company to extend the Centennial tunnel to the San Jose ground, thus draining it. The Centennial tunnel is 2000 feet long now, and would have to be run 5000 feet farther to tap the San Jose. This done, however, the San Jose people could hoist the gravel through a shaft, and not have to pump. The San Jose people have true grit, and have no intention of giving up. They spent over \$10,000 last year, and are willing to spend as much more. They have seen enough of their mine to know that it is worth spending money on, as every car of the gravel pays. If the tunnel project is deemed too big a job, they will probably sink an incline shaft and make it large enough to put in big pumps.

A Bio Crushing.—*Union*: The lessees of the Wisconsin mine are having crushed 76 loads of ore at Joe Southern's mill, and a clean-up will doubtless be made the latter part of this week. The ore, it is expected, will pay as well as former crushings, which have been remunerative.

Good Cleanup.—*Telegraph*: A mighty good cleanup has just been made from ore crushed at Joe Southern's and which came from the Wisconsin mine. The rock was taken out of the north drift at the depth of 225 feet and there were 65 loads of it; the yield was \$53 per load. There now remains upon the dump about 70 loads and they are being hauled to the mill as fast as possible. The mill is kept constantly running on the Wisconsin rock.

Drain Tunnel Completed.—*Transcript*: The drain tunnel upon which work has been going on at the Nevada City mine for some time past has been completed, and the work of opening a station on the 500 level has been commenced. When this is finished the shaft will be sunk another 100 feet. The mine is looking well throughout.

Will Start.—*Telegraph*, March 6: The Granite Hill mine will resume operations to-morrow, and Denver Weggoner has been appointed the superintendent of the mine in place of Stephen Fowler, resigned. Mr. Weggoner will give his undivided attention to the work, and hopes to have the mine, which is now filled with water, running at full blast in a short time. The mine is looking well, and slate has been encountered.

Ten Stamps Needed.—*Telegraph*: The W. Y. O. D. mine is just now looking so good that the management has decided to erect ten stamps more to assist in crushing the ore now coming from the mine. The W. Y. O. D. has all the modern appliances in its mill and when the additional ten stamps begin to drop, look out for big dividends.

The Odin Strike.—*Transcript*: The strike made at the Odin mine a few days ago is of

much more importance than was at first supposed. The gravel has been prospected a distance of 50 feet and found to be rich the entire distance, being remarkably so in spots. It will require about two months work to get the mine in shape for taking out much gravel, and then dividends will soon follow.

Plumas.

Quartz Discovery.—*National Bulletin*: We received recently about 50 pounds of very good looking quartz from the Mountain Chief location on Mill creek, about four miles from Quincy. The owners of this property are Messrs. Kenneth McDonald, Geo. Ellis and Jo. S. Rodgers. The vein was discovered about five years ago, but the fact was kept a secret until three weeks ago, when the vein was discovered on top of the hill through which it runs. The length of the vein from the bed of one ravine to that of the other is about 700 feet, and its altitude above the two streams is nearly 350 feet at the highest point. The owners have been sinking a prospect shaft and are now down 16 feet, the ledge at that depth being between four and five feet, only slightly inclined and between well-defined walls. They claim to have some very rich ore, and that out of 35 pounds of it crushed in a mortar by hand, they secured \$4.50. Of course, this must have been picked rock. However, they claim that all parts of the vein show rich prospects. In the same vicinity, Frank Vere and Mr. Lowe have locations which they think a great deal of.

Riverside.

Good Strike.—*San Bernardino Courier*: Another rich strike has been made in Riverside county, near Salton. P. M. Living came in and brought three large specimens of quartz. The gold is visible to the naked eye, and under gaslight fairly glitters. The mine from which these specimens were taken is known as the Summerville mine. The property has been worked for about two years by the owners, but has never been known to yield very rich ore till a few days since, when a strike of unusual richness was made on the 200-foot level, from which these specimens were taken. The mine is about eight miles north of Salton, on the Southern Pacific, and will doubtless be the making of a fortune to the owners. At present they are working only a few men and have no machinery, but they will continue to develop their interests, and have given out that the property is not for sale. This discovery will probably cause a rush to that vicinity. There is a number of men prospecting in the neighborhood, but no strike of importance outside the present one has been reported.

Good Ore.—The main shaft on Governor Blasdel's Santa Rosa mine, near Perris, is now down 225 feet. A station has been established at that point, and from it a force of men is at work night and day drifting north and south. Between the upper level at 125 feet and the lower level the vein has enlarged from two to over three feet, and an excellent grade of ore is exposed the entire distance.

San Bernardino.

Shadow Mountain.—Of all the mineral-producing districts contiguous to Venderhilt, says the *Star*, none have attracted more attention in mining circles here during the last two months than the Shadow Mountain country. There has been no great excitement connected with it, but instead, its growth in public favor has been steady and gradual. "Shadow Mountain," says a prospector of that section, "is the poor man's country, for the reason that there is rich rock from the grass roots down. The veins are large and the ore rich, and it is bound to be a good place. There are more men coming in every day now, and very few are going out. Everybody is doing well."

Placer Mines.—For some time it has been known by people of this vicinity, says the *Rialto*, San Bernardino county, *Fruit Grower*, that there were some placer mines being worked in Lytle Creek, and that some of them were paying fairly well. The old Turk & Banks mine has been one of the good paying properties. On Tuesday of this week James Washington dropped into our office and showed us some of his fine nuggets as one would wish to look at. He has been working his mine for some three years, and has at no time worked at a loss. Most of the time when at work he has taken out \$3 to the man per day, and this, too, in a very crude way with the old-fashioned rocker and with no modern appliances whatever. Mr. Washington is a colored man, who, as we said, came here three years ago, \$100 in debt, but he don't owe anybody now.

Shasta.

Pounding Good Ore.—*Courier*: Mr. Janney, of the Minnesota mine, on Spring creek, says about ten men are employed at the mine, and the ten-stamp mill is busily pounding away on good ore. The new management has run a 125-foot incline on the mine, and also advanced the tunnel the same distance, and have encountered a body of fine ore.

Siskiyou.

Five Coal.—The Siskiyou coal mine at Windy creek, near Ager, shows some fine coal prospects lately, with steady improvement in the tunnels as the work progresses. At present a ledge of superior coal has been found, measuring over 34 inches in thickness, and fine for blacksmiths' use.

Sierra.

Plenty of Snow.—*Messenger*: It is well worth one's while to take the trip from Downville to Sierra City now. Every ravine and canyon on the south side of the river (opposite the road) has its snowfields, some of which are acres in extent and many feet deep. One in particular that came down Avalanche ravine is a monster. The ravine was not big enough to hold all the snow that slid and the slide divided on a point, part going up the river and part down. The

half that went down has filled up the entire river to a depth of 100 feet, under which the water has eaten its way. This is said to be the biggest snowslide ever known to have come out of a ravine that is famed for big slides. The cabin of the Italians managing the wood tramway was moved from its foundations and part of the Tecumseh flume carried away by another slide.

Stanislaus.

Not Exhausted.—The placers that made the town of La Grange, in this county famous in the early days, have long been supposed to be exhausted, says the *Modesto Herald*, but H. L. Dominici and Eli Leach have found a strip of ground that has heretofore been overlooked and considered valuable only for agricultural purposes. This strip is on the north side of the Tuolumne river and is about a third of a mile long by 150 yards in width, with the bedrock from 15 to 20 feet down. The gentlemen named are mining the deposit by the old-time flume-washing process, and it is related that the surface earth is yielding at the rate of 12 cents to the wheel-barrow load, the pay increasing as depth is attained. In bygone years rich clean-ups were made from the bedrock in this locality.

To Open a Claim.—*Journal*, March 14: Newt, Lamb and Bee Lee are making preparations to open a blue gravel claim farther up the creek than the Austin & Co. claim, and are getting firewood hauled upon the ground with intention of procuring a first-class steam engine from Chicago to hoist gravel and work the pumping machinery in keeping the claim drained of water. They have some machinery already on hand for the purpose.

S. S. Cooley, in hauling away the dirt shoveler from the corner saloon opposite the post-office in Yreka, for a cellar, found two small specimens of gold, and could no doubt find more by washing the ground taken away, although it was not near enough to bedrock to pay rich. The entire townsite of Yreka is located on rich ground, at bedrock, but the patent obtained prevents any mining, except what can be done by owners on their premises without injury to adjoining property. The bedrock ranges from 15 to 30 feet below the surface, and contains such an immense quantity of water as to require powerful steam pumps for draining the same.

From Sawyer's Bar.—*Cor. Journal*, March 14: March came in like an enraged lion with plenty of snow for a good water supply, giving assurance of a splendid season for mining in the Salmon river region.

The Jumbo Company has shut down operations for awhile, and the property is about to change hands.

Golden & Eveleth have resumed work in their quartz mine, having been interrupted by the deep snow.

Monkton & Co. are almost ready to start work again very soon at their mine. Hall & Co. have completed their ditch, with the hydraulic pipe laid, for starting the giants.

The old Black Bear quartz mine has not looked as well in ten years past as at present, a new strike of high-grade ore having lately been found.

Campbell & Wagner had a short run on the old Grattan mine, meeting with good success. They were prevented from further washing by the water freezing, and have since been taking out quartz to be ready. Their prospects are certainly very flattering.

The Red Hill mine, on Know Nothing creek, paid handsomely at the last clean-up, under the able management of P. T. McManus.

Dougherty Bros. are working off pay ground at a great rate, but it is rocky, though paying well.

John Barry and Wm. James have completed their flume and race, and are now busily at work sluicing down rich pay gravel.

Mr. Sallee made a clean-up of \$1100 at his claim.

Hamilton & Henry's mine is lying idle at present, but will soon be started up.

Trinity.

The Quicksilver Mines.—*Dunsmuir News*: The Integral quicksilver mine has been running all winter and a large stream of quicksilver is continually pouring from the mouth of the furnace. This mine has developed into the richest quicksilver mine in the country, and is giving employment to a large force of men. The old Altoona mine, in the same locality, will start up in a few weeks. It is another very rich piece of property and has a whole mountain of ore in sight. This property has been in litigation for years, but that is all settled now and the property will be worked for all it is worth. There will be a large force of men working in that country this summer.

Tuolumne.

In Running Order.—*Independent*, March 10: The Rawhide mine is again in full running order. The vast amount of water that gained access to the Jack Rabbit shaft and levels from old Rawhide shaft and stopes has been reduced sufficiently for active work to be resumed in the levels and stopes. Two steam pumps and skips have been constantly hoisting water for the past several weeks. The miners are now breaking out the usual rich rock and filling up the ore bins, preparatory to starting up the mill on Monday next. The company is preparing to place the water, for power, to run all the machinery, also for pumps, hoist and mill, on the top of Table mountain. The water will be conveyed in large steel pipes to the works. This new and most necessary departure will provide all the power needed for the present and future development of this still wonderfully rich mine. A supply of firewood will be kept always on hand, in case of breakage of ditch, flumes, or pipes. This is a safe precaution, and is a sure auxiliary in case of need.

The Cardinelle.—This once famous mine, from which some \$300,000 was extracted in the

early days of mining at Tuttle town, is now showing unmistakable signs of the near approach to a pocket. Thursday a small vein—a counter—was found striking into the main vein, which is from two to four feet wide. We were shown several samples of rock freely covered with gold, which were found at a point where the rich metallic slate had also come in. This augurs well for a rich development near at hand. The company has been working at considerable cost, and has sunk over 200 feet prospecting. It is in a drift north 109 feet, where the present prospect has been found—the first gold seen since the plucky owners have been so assiduously working for the past 15 months. From this point to the surface there is fully 190 feet of virgin ground. All the necessary crossings and gold seams are being found near this point of contact.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—In his official report of last week's work in the Consolidated California & Virginia mine Superintendent Lyman says: "1650 level.—No work has been done in the drift run north from the foot of the upraise on the sill floor of this level. From the end of the crosscut running east—68 feet in from the drift run north from the east crosscut No. 1 from the north drift from the winze—down 52 feet—a north drift has been started and advanced 12 feet in a porphyry, clay and quartz formation of low assay value. Have extracted in our workings in the vicinity of the winze—down 20 feet—18 tons of ore assaying \$38.50 per ton. Have shipped to the Morgan mill 517 tons and 120 pounds of ore, the assay value of which, per car sample, was \$38.08 per ton. The assay value, per battery samples, of the ore worked at the mill during the week (610 tons) was \$33.78 per ton. 1000 level.—At a point 353 feet south of the shaft station the upraise has been carried up 30 feet. The sill floor sets of the upraise, as already reported, showed streaks and bunches of ore of fair value. In working upward we passed through the ore into quartz and porphyry assaying from \$2 to \$10 per ton. In the top of the raise openings the formation is porphyry, clay and quartz of some assay value. The east crosscut No. 2, started at a point in the south-west drift at a point 527 feet from the shaft station, or 117 feet north from the Best & Belcher connection, has been advanced 40 feet, passing through porphyry, clay and quartz formation of low assay value."

In the Best & Belcher mine, on the 900 level, the east crosscut on the north boundary has been advanced 18 feet, passing through porphyry and seams of clay; total length, 392 feet. In the Gould & Curry, on the 200 level, west crosscut No. 5 was advanced 14 feet. The face is in porphyry. In the Andes mine, on the 420 level, west crosscut No. 3 is in 70 feet. Formation, clay and porphyry.

In the Ophir mine no changes are reported in the 1465 level workings, except that a new west crosscut has been started from the north drift 142 feet from its mouth, and has been advanced 15 feet in porphyry, clay and quartz. An advance of 84 feet has been made during the week in reopening and repairing the Central tunnel, making the total length of the drift reopened from its mouth 884 feet. Have continued (jointly with the Mexican Company) the work of making repairs to the main shaft. In the Mexican mine, the upraise near the mouth of the west crosscut on the 1465 level has been carried up 23 feet, and continues in porphyry and quartz of some assay value. On the 900 level of the Union shaft the joint Union Con. and Sierra Nevada east crosscut is in 134 feet. The face is in tough clay.

In the Hale & Norcross mine, in working off from the winze below the 1300 level, they extracted the past week seven cars of ore, assaying \$18.21 per ton per car sample. In the Kentucky Consolidated mine, on the 1100 level, the incline raise from the south for an air connection is up 18 feet in quartz of fair grade, with bunches of good ore. 1200 level.—Have started in this level a joint lateral drift with the Yellow Jacket running south in the west ledge; face in good ore of fair grade. In the Alta mine on Wednesday last the raise reached the height of 100 feet, and at that point they started a drift south in the vein. This drift is now in nine feet; face in porphyry, clay and quartz. They are making a connection between winzes No. 1 and No. 2 at the depth of 24 feet, and saving a little ore of fine quality; average value of car samples, \$30 per ton.

In the Sierra Nevada mine the south lateral drift from the intermediate tunnel has been advanced 17 feet; total length, 484 feet; face in hard porphyry. Are putting in a line of pipe from the Union shaft to convey compressed air to the tunnel, which will enable them to use machine drills and make better progress. The joint east crosscut, near the north line from the north drift, 1520 feet west of the shaft, 900 level, has been advanced 22 feet through heavy clay; total length, 134 feet.

CARBONATE OF SODA DEPOSIT.—*Enterprise*, March 8: The vast area of white sand on the plain east of town, which is a familiar object to every resident of the Comstock when viewing the landscape to the eastward and designated as the alkali flat on the desert, and which in certain conditions of the atmosphere resembles a lake in the midst of the vast plain, has recently been located under the mining law in 20-acre sections. There is every evidence that at some remote period this plain was a vast inland sea, the level of which is distinctly marked by a line of marine shells along the range of hills marking its northern and western boundaries. Acting upon this theory, a local prospector, who is as familiar with geology as mineralogy, concluded that the so-called alkali flat, being the lowest point on the plain, was the last place the receding waters of the inland sea occupied before they finally vanished. This

conclusion was natural, as the surrounding country is covered with a thick growth of sagebrush, gradually growing thinner until it reaches the boundaries of the sand flat, on the surface of which there is not a vestige of vegetation of any kind. A shaft sunk in the sand showed a stratum of marine shells and other formations usually found in the bed of lakes and at a depth of six feet a deposit of carbonate of soda was encountered which is of unknown depth, as it still showed in the bottom when the shaft was down to a depth of 12 feet below the surface. Tests were made at various places on the sand flat and all showed that the carbonate deposit extends throughout the entire area, which includes several hundred acres within its boundaries, and demonstrated beyond doubt that the deposit is of vast value. The locator is now negotiating with an Eastern firm for the sale of his ground with a fair prospect of success.

CARSON DREDGE COMPANY.—A meeting of the stockholders of the Carson River Placer Mining and Dredging Company was held in New York City on the second of this month.

The stock of the company was increased to \$2,000,000, and a block of this stock, sufficient to pay all debts and complete the proposed plant, was offered to parties interested at a specified price, the remainder to be reserved until the present plant shall be paying dividends, and then be sold only for putting in more new plants.

The plan of the company is that of concentrating the material raised, and also milling the concentrates, with supplemental arrangements for saving the free material. The company proposes to put in an electric plant to furnish the power, and this, together with the concentrating plant, will require an expenditure of something over \$20,000.

In view of the above facts the Lyon County Times considers that the prospects of the Carson River Placer Mining and Dredging Company never looked better.

J. C. Pierson, now superintendent of the Sacramento Gas Works, will succeed Dr. O. H. Warren as manager of the company, and Captain H. Davis will act as superintendent.

Comet District.

GREAT SILVER MINE.—The acknowledged great silver mine of this section is the Linden, owned by Freudenthal Bros. & Smith, situated in Comet district, 15 miles west of Pioche, says the *Lode*. H. W. Turner and Messrs. Swindler and Lloyd visited the mine during the week, and all express themselves as having seen a great bullion-producer were silver where it should be. The entire work on this property is exclusively in ore that, without assaying, will average \$50 per ton, and a lot of about 30 tons, which has been assayed, will average 20 per cent lead, \$12 gold and upward of 140 ounces silver per ton. The formation is principally lime rock, but the Linden was discovered in a contact of shale and lime, and its discovery is the theory of the district. All the work of the many years past has been on little seams of rich ore and large ledges of low-grade ore, with all the work entirely and exclusively in lime formation. The discovery of the Linden induced the hope to prospect other ledges, and with the knowledge derived from development work on this mine they met with success.

ARIZONA.

BIG BUG CAMP.—Cor. Prescott *Journal-Miner*: Being on a visit to some of the mines in this district, I find the hills are full of prospectors. George Whittaker is extracting \$50 ore from a mine he has leased of Frank Blies and Joe Askew.

Jim Slack, the man who discovered the Yankee Girl (now the Henrietta), has again made a rich strike in the 79, formerly the Lotta. This mine has a shaft 200 feet in depth, with a crosscut tunnel 300 feet in length. The south drift, 150 feet from the top, is in 100 feet on an ore shoot of 2½ feet in width. The ore assays \$140 in gold and 60 ounces in silver per ton. Mr. Slack is working the mine with three men, and is taking out lots of ore which has been milling from \$40 to \$50 per ton, but this strike sends it up into the hundreds. He also has very rich ore in the first level, 75 feet from the top in the north drift. This mine is the best developed mine in the district, except the Henrietta. There have been some Denver parties examining it, with a view of purchasing. A Denver mining man says if he had a mine like this in Cripple Creek, Colorado, \$100,000 would be nowhere, or no price for such a property.

The Dividend mine is looking fine. Messrs. John Andrew and Butler deserve credit for having the stamina to develop such a mine, which has been dormant for ages under a U. S. patent.

John S. Jones' 15-stamp mill is running night and day on ore from the Little Jessie dump, which pays \$9 per ton, a pretty good showing for a paltry dump of several thousand tons.

Tom McDonald and Wm. McCoy have struck very rich gold ore in a mine supposed to be an extension of the 79.

The Henrietta mill, under the management of Nick Palmer, is turning out lots of bullion. Jesse Davis and Len Laphoon have a fine looking gold mine on Big Bug. It is what they call low grade, running \$15 per ton.

SIX CLAIMS SOLD.—Prescott *Journal-Miner*: An important mining deal has been consummated, in which the title to six mining claims on Castle creek was transferred from F. A. Lehman to A. Falco, Colin Timmons, J. M. Watts and H. Blauvelt. The consideration is not given out, but it runs away up in the thousands. The property is a free-gold proposition. The claims are already pretty well developed, but a force of men will be set to work at once, to further develop them. Mr. Blauvelt will have the superintendency and will leave tomorrow to commence operations. The sale of this property, together with one or two other sales that have been made recently in the same

section, will give quite an impetus to Castle creek district. Mr. Falco, who recently came here from Colorado, has manifested great faith in this section, as is shown by the investments made by him. He is a thoroughly practical mining man and has already proven a valuable acquisition to this section.

NEW DEVELOPMENTS.—Yuma *Sentinel*: The Harqua Hala district bids fair to heat her magnificent record of the past year at least 50 per cent. The opening of the Golden Eagle mine in connection with the new developments in the Gold Hill, the double compartment working shaft, the ten additional stamps to their mill—now 40—and other enlarged facilities, the former production of \$50,000 per month will be doubled. Several important discoveries have been made in the camp lately, chief among which is the Delhi claim, near Harrisburg. The find is as rich as anything yet discovered, the rock literally glistening with the yellow stuff. Rarrick and others are showing up good mines. Charles Hall of Goldfield is continuing his developments on the Quinn Broe' mine, an extension of the Bonanza, and no doubt they have a good thing. The Delhi property, adjacent to the Bonanza, is being worked on bonds, and it is a certainty that the transfer will be made.

San Pablo district is situated on the north side of the Gila river, opposite Gila city, and 16 miles east of Yuma. It is a camp that is attracting the attention of the mining classes with increased interest. It is now believed that many of the mines heretofore known to be rich on the surface will be thoroughly developed, and with such results as will prompt activity in various branches of business. It is estimated that there are now 100 men directly engaged in mining and developing in the district.

Parties in from Pot Holes say that the Indian and Mexican miners there are doing a good deal of placing with good results.

IDAHO.

AN ELECTRIC HOIST.—Wardner *News*: The Bunker Hill & Sullivan Company is putting in an electric hoist in the Bunker Hill mine. A number of new ore cars are now en route from Chicago, and as soon as they arrive active work will be done in stopping ore recently found in the west branch of the Reed tunnel. The number of men now on development work amounts to 38. The regular underground force of 200 remains about stationary, with the usual number of new men being put on each day to supply the places of those either quitting or discharged.

MONTANA.

THE COPPER MINES.—Butte *Inter-Mountain*, March 10: The Moulton mine and mill have been closed down again. The Butte sampling works are operating to their fullest capacity and have run more continuously the past two months than ever before.

A great many mines are being worked on a small scale, the miners being in search of copper, while they take out barely enough silver to pay expenses. One notable exception is the Eveline mine, which is regarded as a fabulously rich property, carrying large quantities of pure native, wire silver and gold. It is said the Eveline mine produces the richest ore ever found in this district.

The copper mines are all working as usual. Machinery is being placed in position at the new converter building of the Anaconda Company. The foundations for the five large engines are completed and two of them are in position. Four of these engines will be about 200-horse power each and one about 500-horse power. Men are putting them up as fast as they can get the machinery, which is arriving very slowly. The boilers are nearly all in place. There are to be six large boilers, all but one of which is there, and in one of them steam is constantly kept up. The greater part of the power developed by these engines will be used on the six air compressors for the converter in the building above. There are six stands ready for converters in the building, on four of which the converters are already in place, and the others can be put in at any time.

OREGON.

ANOTHER MILLING PLANT.—Baker City *Democrat*, March 5: Messrs. Logan & Young, miners on Upper North Powder, go to Athena, Oregon, to arrange with the other partners, Messrs. Dr. King and Answorth, of that place, to buy and erect a mill the coming season on their valuable property. Their mine, the "Illinois," assays from \$20 to \$75 to the ton.

NEW MILLING PLANT.—Baker City *Democrat*: Among recent arrivals in Oregon's Denver is Mr. J. G. Chapman, of Arcata, Cal., who is here to look after important mining interests. Mr. Chapman and Mr. B. Doe, of San Francisco, have a bond on the Pyx mine, situated in the Robinsonville district, about 40 miles southeast of the city. The mine has been worked all winter and the results have been most satisfactory to all parties concerned.

The gentleman has a milling plant here, which he shipped from San Francisco, and it will be shipped from the mine at once, Mr. Thos. McEwen having been awarded the contract for hauling the machinery from McEwen to the millsite. Mr. Chapman says that the tunnel is in 415 feet on the Pyx mine, and a shaft taps the ledge at a depth of 160 feet. The vein is two feet wide and the ore assays from \$20 to \$250 per ton. Only five stamps will be used at present, but five more will be added in a short time and it is probable that before the year ends the plant will be running to its fullest capacity, dropping 20 stamps.

STARTED UP A MILL.—Jacksonville *Times*, March 12: The Lucky Bart Mining Company have started up their mill, which has been idle for some time owing to the unfavorable weather.

Dr. J. Hinkle of Central Point is developing

a quartz mine in Sardine Creek district, which promises well. He thinks that he has a genuine fissure ledge.

The Annie mine in the Bohemia district has shut down until the snow settles, when there will be some improvements made. It is reported that McGee & Co. took out nearly \$5000 in their short run.

The placer mines in Foot's Creek district are running on full time and the miners are much elated over the prospect of a good cleanup. The season's output for this district is expected to reach up well toward the \$600,000 mark.

WASHINGTON.

THE METALINE PLACERS.—Spokane *Review*: Placer mining on the Pend d'Oreille river, in the eastern portion of Stevens county, promises to assume great proportions during the present year, and the property owners in that district expect to see a large population in the town of Metaline before the summer season is half over. Eastern money is already finding its way down the river from the Great Northern from Newport, and already the Newport Transportation Company is making preparations to build a large steamer to carry the traffic. The people of the Colville valley are also becoming enthused and are taking an active interest in pushing a wagon road through the range from Colville to Metaline, a distance of about 40 miles. The miners in the Metaline are making good wages by the use of rockers, with an inexhaustible field of pay dirt to operate upon.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PAPER U. S. and Foreign Patent Agency, the following are worthy of special mention:

CAR VENTILATOR.—Thos. E. Merrill, Oakland, Cal. No. 516,058. Dated March 6, 1894. This invention relates to that class of ventilators especially adapted for cars and other moving vehicles, and in which a rotary fan driven by the exterior air currents is employed to exhaust the foul air from the car or vehicle. It consists in a casing having a passage through its lower portion from end to end, and an opening in the upper portion of its inner side, exposed to or in communication with the interior of the car, and a fan mounted in said casing and exposed at its lower portion to the current of air which passes through the bottom passage of the casing whereby the fan is rotated and the fine air is sucked out through the side opening of the casing and discharged by the fan through the bottom passage.

FILTER.—Wm. Weir, S. F. No. 516,140. Dated March 6, 1894. This invention relates to that class of filters in which a single valve, provided with two or more ports, controls the inflow or exit of water from a chamber containing suitable filtering media, it also combines the use of a simple hub for draining unfiltered water for household purposes by turning the plug in an opposite direction from the normal in draining filtered water, thus saving the cost of a superfluous hub.

HORSESHOE.—Z. Birdsall, S. F. No. 516,046. Dated March 6, 1894. The object of this invention is to provide a shoe with front toe calks formed on the line of curvature of the foot of the shoe and separated from each other, and a series of pointed calks of different elevations extending around the periphery of the shoe to the heel, with a projecting ledge for the oil holes. Shoes made in this manner may be used in the winter season until the points are worn down, when the shoe may be taken off and laid away for use in the summer as a flat shoe.

A CAN BODY-MAKING MACHINE.—Clarence M. Symonds, Sao Francisco. No. 516,033. Dated March 6, 1894. This invention relates to improvements in the manufacture of can bodies. It consists of a mechanism whereby the sheet of tin is taken and bent up into a partly cylindrical form: then has hooks formed upon its edges adapted to interlock; is then carried forward and these hooks interlocked; then compressed or locked together to form a cylindrical can body. The movements are intermittently and successively produced by the reciprocation of a bar or body around which the tin is bent to form the can.

A SLIP-CUTTER FOR INDEX PURPOSES.—Alexander J. Rudolph, Sao Francisco. No. 515,119. Dated March 6, 1894. This invention relates to a device for cutting slips for index and library purposes. The object is to facilitate the cutting of entries from printed works for insertion in the leaf-holders of index and file devices. In making up these leaf or slip-holders, catalogues, journals, and other works which have already been printed are utilized by cutting out the lines which it is desired to employ in the index. When very narrow spacing is used, as with nonpareil type, the apparatus makes a neat separation between the lines. It consists of a cutter, movable with relation to the table upon which the sheet to be cut is placed, and gauges by which the slip is accurately placed with relation to the cutter.

STEAM ENGINE.—Eugene Shydecker, Sao Jose, Cal.; assignor of two-thirds to Jobo H. Moore, Sao Jose, Cal. No. 516,064. Dated March 6, 1894. This invention relates to improvements in steam engines. The object is to combine in a single apparatus mechanism for utilizing the steam directly from the boiler to an initial high-pressure cylinder, exhausting it into a second cylinder, where it is utilized to drive a piston, which in turn acts on its return stroke to pump the steam into a super-heater from which it is again delivered to a third cylinder, where it acts upon a piston, and finally passes thence into a reactionary wheel mounted upon the engine shaft, being finally exhausted from this wheel. The whole apparatus is designed to utilize the power of the steam to its very last profitable limit of expansion, and during this process of expansion to superheat the steam so as to restore its elasticity, which is partially lost during the expansion.

The Union Inclined Ropeway.

The illustrations on this page are designed to show the workings of an inclined self-acting ropeway, and a new device for its control, manufactured by the Union Iron Works. The lower cut shows the former method; the upper, the new terminal. The illustrations are so clear as to be self-explanatory.

By the system shown in one the rope passes over a supporting sheave and around the upper terminal to which the brake is applied. The improvement consists in making the supporting sheaves and guide sheaves one, and rendering the movement of the rope firm and steady by a reverse turn over the upper vertical sheave. The brakes are applied to the lower sheaves, whose motion is in opposite directions.

A NEW QUARTZ CRUSHER, known as Davey's patent ram hattery, is reported from Australia. The machine is a simple adaptation of a one-stamp mill, the only difference between it and the ordinary hattery being in the formation and construction of the box, which in this instance is of a cylindrical form and made of $\frac{1}{2}$ -inch boiler plate iron instead of cast metal. It is in two sections, strongly bolted together at the angle joints. A cast steel shafting passes vertically through the center of the box, to the lower end of which is attached the stamp head, the upper end being connected by a shackle and chain to an overhanging spring beam. To the top of the cylinder is bolted a circular iron plate, upon which a man stands to work the shaft and thus impart the necessary action to the stamp. The stamp head is of chilled steel, and weighs about 200 pounds, the total weight of the machine altogether being

in the neighborhood of 850 pounds. All the working parts are of cast steel, and everything about the crusher is so constructed as to be quickly taken to pieces and as easily re-erected. The patentees claim that it will treat

from one and one-half to two tons of rock per eight hours.

It is interesting to note that the determined fight by the miners of New South Wales for private ownership of mining property is at last making headway, and that the legislative council is about to pass a bill having that object in view. The measure is a violent departure from the policy of land ownership which has heretofore obtained in Australia, and for that reason encountered the bitter hostility of the great landlord class. It is not expected that the measure as it passes will be perfect, but it will be an entering wedge, and desired changes can hereafter be made as needs require. The mining laws of the United States are a very long way from what they ought to be; but the principle of private ownership is firmly established here, and when title to mining ground is once obtained it is as secure as any other.

THE stimulus given to gold-mining operations during the past year has been of great benefit to the development of Oregon mines. It is confidently stated that the gold output for 1893 was larger than ever before—it probably reached \$2,000,000—and during the present year a very much heavier yield may be expected. Oregon has been a severe sufferer during the present depression. Its chief industries have been the production of wheat and, in eastern Oregon, of wool. Both these are depressed to an unprecedented degree. The activity in mining stands out brightly in the midst of the general stagnation.

MINING SUMMARY.—From the Various Counties of California, Nevada and other Pacific Coast States and Territories, 189-90.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 191.

It is claimed at Cripple Creek that the new bromine process of Prof. Englehardt has succeeded in saving 95 per cent of the assay value of the ores and that the cost of treatment by his process will vary from \$2.50 to \$6 per ton.

Wood is reported very scarce in Nevada City. Owing to the rain and snow, the teamsters are unable to haul fuel from the woods to town, and the local supply is well-nigh exhausted. The price has now reached \$8 a cord. Many families are said to be burning boards and scraps of all kinds.

PERMITS to mine by the hydraulic process have been issued by the California Debris Commission to the Spring Gulch Gold Mining Company, operating the Spring mine at San Andreas, Calaveras county, and the Kate Hayes Mining Company, operating a mine at French Corral, Nevada county. In all, the Commission has received 54 applications and has issued 24 permits.

THE managers of the mining exhibit at the Midwinter Fair calculate that at least \$2000 more will be necessary to carry on the exhibit, and it is to raise this sum that an appeal is now being set forth. At the beginning it was proposed to raise \$10,000. The amount raised was only \$7578.10. It is thought that the mining men of the State ought to come forward to make the sum \$10,000, and to insure the successful carrying on of the greatest mining exhibit, in the opinion of experts, ever collected. Unless the money shall be raised it will be necessary to run the mill a very limited time each day, as well as to place the exhibit under other restrictions, which would seriously impair its usefulness.

It is extraordinary that the United States Government has no department especially devoted to promotion of the mineral interests. The mining industry in this country, in its various branches, is hardly less important than agriculture, to which the services of a Cabinet officer and a department are especially devoted. But there is nothing of the kind for the mines, not even a bureau. The Geological Survey is attached to the Department of the Interior, and the collection of statistics and general information is a part of the duties which devolve upon the Director of the Mint, who reports to the Secretary of the Treasury. It is not too much to say that the government cares less for its mines than for any other industry equally great.

He Will Use the Veto.

CHICAGO, March 22.—A Washington special says: The President will veto the Bland bill. He reached this conclusion last night. He has prepared the draft of the veto message, and will submit it to the Cabinet to-morrow. For this statement there is the authority of one of the closest financial associates of the President.

Activity in Gold Mines.

The expectation entertained a year or two ago, and freely expressed in these columns, that California was on the verge of a general revival in gold mining, is being pretty fully realized, as we all know. More capital has been invested in mining properties during the past year than for several years preceding. The aggregate was no doubt to some extent restricted by the financial depression, though the paralysis of other industries was a very strong reason so much attention was paid to gold production. The various foundries and machinery agents in this city report that there is more proportionate demand for quartz-milling machinery than for any other kind. As a matter of fact, they have not done a great deal besides repair work in other lines. The recent sale of the Good Hope mine, in Riverside county, for \$500,000, and the purchase of a twenty-stamp mill from the Union Iron Works, is a case in point. The syndicate of which Dr. Stephen H. Emmens is the head has made heavy investments in Amador county, and has just purchased another mine—the Normandy—in Nevada. The McCaw brothers propose to do something with the famous Hite mine in Mariposa. A syndicate has just bought the Gwin mine, in Calaveras. James D. Hagne has made extensive purchases in Nevada county. The well-known Alison Ranch, a heavy producer in times past, is believed to have been purchased by capitalists, and will be re-opened. The La Grange company has made enormous investments in Trinity county for the development of newly-acquired property. The Plumas-Imperial Mining Company the Quincy Water and Mining Company and the Kate Hayes Mining Company have made large expenditures to develop their hydraulic properties in Plumas and Nevada counties. And there are many others. The list given is named as they occurred to the writer. They are mostly instances of actual development.

No doubt even more will be done during the present year. The hydraulic mines have got a fair start toward resumption. Quartz properties are being very generally inquired after. Drift mining is being more largely engaged in than ever. The outlook is, we think, exceedingly good for California mines.

Coining Silver Bullion.

The Bland bill, which has passed Congress and now awaits the President's signature, provides first for the coining of the "seigniorage"—the difference between the real and nominal values of our silver coinage—and thereafter of other bullion purchased under the Sherman act of July, 14, 1890.

Experts are beginning to discuss the methods by which the bill will be put into effect, if signed by the President. It is understood that the mints throughout the country, immediately after the bill is signed, will begin the work of coining silver dollars out of bullion. It is estimated that it will take about four years to do this work. It is thought, however, that were the bullion distributed among three mints in proportion to their capacity the work could be completed in much less time, but the cost of transfer, it is believed, is too great to make this distribution advisable.

As stock is held at present, San Francisco, coining \$1,000,000 a month, would take 16 months to finish its stock. It would take the New Orleans mint 12 months at the same rate of speed. The balance of the bullion, amounting to 118,000,000 ounces, or, when coined, \$150,000,000, is at the Philadelphia mint, and unless an extra shift of men be put to work it would take five years, it is estimated, to coin its stock and, at the same time, do such other work as occasion might require. In view of the fact that it costs \$5 per thousand to transfer silver from Philadelphia to New Orleans, and \$8 to San Francisco, it is not likely that this shift will be made.

In this connection it is interesting to state that the present stock of bullion cost the Government \$126,000,000, the average price per ounce being 90.9 cents. This bullion, when coined, will make \$180,000,000, the difference of \$54,000,000 being what the Bland advocates call the seigniorage or profit. It is this seigniorage for the coinage of which the proposed law provides.

It is also stated that were the stock of bullion on hand to be purchased at the market price to-day it would cost but about 60 cents an ounce, a difference of 30 cents. This would make the total stock on hand cost but \$84,000,000, or \$42,000,000 less than was paid for it, or \$93,000,000 less than what Bland maintains the present stock of bullion coined will make.

THE tariff bill has been reported to the Senate in substantially the same form as amended by the sub-committee. Quicksilver and crude or borate of soda, or borate of lime, are on the free list. There is no change in the 4 cent duty on lead, as well as iron and coal.

California Mines at the Midwinter Fair.

Butte County.—The design of the collectors of Butte county's exhibit at the Midwinter Fair appears to have been to show the variety of its mineral products and to emphasize, by ocular evidence, their special characteristics as well as their usefulness. The most active quartz-mining district in Butte county at the present time is Forbestown; therefore a great mass of ore from the Gold Bank mine occupies the place of honor in the center of the exhibit. The characteristic of Forbestown ores is the presence of sulphurets in large quantity, and these specimens are finely adapted to display their character. Large clusters of sulphurets appear on the surface of the quartz, so conspicuously as to attract immediate attention. One chunk of ore weighs 2900 pounds, being one of the largest in the whole mineral collection. Other features of this exhibit, outside a large general collection of ores, are specimens from the river mines and hydraulic mines of the county, and 53 collections of sulphurets in their various forms from the time they are taken from the concentrator until they are oxidized after leaving the furnace.

It is proper in this place to make mention of the Forbestown district, which appears so prominently in the exhibit, whose merits are extolled by the well-informed gentleman in charge, Mr. Frank Early. The Forbestown veins were worked many years ago, but, on account of the "rebellious" nature of the ores, they were abandoned. The quartz yields only a few dollars in free gold, bearing four per cent of sulphurets, more or less. Appliances for working such ores were not so efficient then as now and the district, after enjoying a great deal of activity, was practically abandoned. Within the past few years, however, Forbestown has again attracted attention; and a determination on the part of practical mining men to resume mining operations has been carried out with great success. Chlorination has effected the desired objects. Results secured at the Gold Bank—the chief mine in the district—may be used for illustration. The ore bears about \$4 in free gold and four per cent sulphurets. These are worth \$250 per ton. The value of the sulphurets per ton of quartz is therefore about \$10, which, added to the \$4 free gold, makes a total of \$14. Forty stamps are dropping day and night in the mill, and the chlorination works have a capacity of eight tons per day. The capacity of the mill is 110 tons per day. The daily payroll—mine, mill and chlorination works—is \$200 per day. If these figures are correct—and they are said to be authoritative—the total labor cost of mining, milling and chlorination is less than \$2 per ton. They teach, also, another useful lesson, viz.: It would doubtless be possible to make a profit out of the mine and throw the concentrates away, which could not be done during the former period when the mines of the district were worked. Both mining and milling appliances have shown great improvement since that time.

Sulphureted quartz from the Shakespeare and Golden Queen mines of Nickerson & Vail, Forbestown, are also shown. They have precisely the same character as the Gold Bank ores, and are doubtless worked as profitably.

Fine specimens of ore from the Banner mine, on the west bank of the main Feather river, are displayed. It is interesting to state that this mine, which had been abandoned, is under the management of Col. Frank McLaughlin, and its value has been successfully demonstrated. It is said that the mine yielded \$680,000, but the vein pinched out completely at the 300 level. There was evidently a fault in the ledge. Various unsuccessful attempts were made to find the ledge. Finally, Col. McLaughlin took hold of the property, sank 200 feet vertically into the country rock, crossed it, and found the ledge in place. Arrangements are now going forward actively to develop the property. An electric plant will be put in, the power being secured from the old Miocene ditch, three miles distant, whence it is transmitted to the mine. A 10-stamp mill and all works necessary to the systematic development of the property are to be installed.

The quartz from Butte county mines is by no means deficient in free gold. Many specimens of the latter kind from working mines are shown. From the Phoenix mine, at Hurleton, very fine quartz averaging \$12 per ton is shown. There is also a collection from the Standard, of the average value of \$20 per ton.

There is a variety of gravels from several hydraulic mines, the most interesting of which is, perhaps, a collection of 12 boxes from the famous Cherokee mine. These show the different strata encountered in the development of this gravel property. It is well known that its working by the hydraulic process was abandoned partly because the bank became about 500 feet in height and it was too expensive to handle the great mass of gravel. Litigation also did its share toward securing suspension of operations. Works are said to be under construction by which the mine will be opened by the drift process.

Two boxes of gravel from the Golden Feather mine

call to mind the most interesting achievement of mining operations in Butte county and the most elaborate and expensive attempt now being made—if not ever made—to work the river channels of the State. In connection with the Golden Gate, an adjoining claim on the Feather river, a vast sum has been expended. A summary of the work necessary to be done before actual mining operations could begin may be given: First, there was the building of ten miles of substantial roads; the providing of dwellings in three separate camps capable of accommodating from 150 to 300 men, besides the necessary workshops; also the building of a canal along the right bank of the Feather river, 40 feet wide and 6000 feet long, requiring the excavation of 50,000 cubic yards to carry the river when turned out of its natural bed; the construction of a permanent head dam; the procuring of power, which was obtained by repairing the old Miocene ditch, which required five miles of iron piping; also the erection of an electric plant, to enable the work to be carried on by night as well as by day, and the connection of all the different points and the ditch stations with the head offices by telephone, requiring over 40 miles of telephone wire.

In the construction of the canal, a cemented rock wall was carried along the entire distance next the river, at a width of four feet on top and twelve feet on the bottom, reaching, in places, a height of over 20 feet from bedrock, containing over 10,000 cubic yards of masonry; in the construction of which 6000 barrels of Gillingham cement were consumed, costing \$4.68 per barrel laid down at the works, bringing the cost of the wall up to \$7.50 per yard.

Two suspension bridges cross the canal, giving access to the work from the shore. One of the bridges is 80 feet long, carrying the pipe-line across that conveys the water power from the Miocene ditch. The company has the use of 1000 inches of water in return for repairing and keeping the ditch in order.

The head dam of the Golden Gate claim, about 2½ miles above Oroville, has a total width of 374 feet and a height of 52 feet. The works are in many respects similar to those of the Golden Feather. Ool. McLaughlin is manager for both companies, whose stockholders are English.

Other features of which mention should be made are the display, in the general State exhibit, of fine specimens of river, placer and leaf gold, and five small pieces of platinum, which were found in the Oberokee mine. Kaolin from an extensive deposit three miles above Oroville is also shown. It is said the presence of this deposit of kaolin has been traced ten miles.

A summary of Butte county's whole exhibit is contained in the following:

Gold-bearing quartz, showing free gold, from the Standard mine; sulphurets from the same mine; gold quartz from the Gold Bank mine, carrying four per cent sulphurets; gold quartz from the Mascot mine of Oregon City; gold quartz from the Golden Queen mine of Forbestown, rich in sulphurets, worth \$202 a ton; gold-bearing quartz from the Golden Banner mine of Oroville, sulphurets, worth \$8000 a ton; gold quartz from the Shakespear mine of Forbestown; gold quartz from the Rainbow mine at Yankee Hill; gold quartz from the Aurora and Argonaut mine at Lompkin; gold-bearing quartz from the Climax mine at Hurleton; gold quartz from the Phoenix mine at Hurleton; gold quartz from the Judge Gray mine at Hurleton, \$8 per ton; gold quartz from the McMillan mine of Hurleton; gold quartz from the Pezleg mine at Oroville; gold quartz from the Williams mine at Yankee Hill; gold quartz from the Myers mine at Enterprise; gold quartz from the Root, Rapp & Bollinger mine at Enterprise; gold-bearing cement gravel from the Bangor, Oregon Gulch, Morris Ravine and Magalia districts, from the Cherokee hydraulic mine and from the Golden Feather mine; marble from the Merrimac district, polished and unpolished; black marble, polished and unpolished, from the Pentz district; soapstone from the Horse-shoe district; sandstone and tufa from the Pentz district; kaoline from Oroville; iron ore from Oroville; manganese from Magalia, carrying 70 per cent; chrome iron ore from the Pentz district; fossils showing shells; lava needles; bowlders washed down by hydraulic mining; crystals; case showing gold, silver, copper, lead and iron ore, 50 specimens; Indian relics, 85 specimens; sulphurets from the various mines of the county, 53 samples; model of the famous Willard nugget found in Butte county, April, 1862; weight 835 ounces; value, \$13,312; model of another nugget, weight 132 ounces; value \$2112; case containing specimens of rock from the various mines, including gold-bearing talc, gold-bearing jasper and gold-bearing chaledony; case of petrifications, including water formations, petrified and agatized wood, petrified potato, petrified chicken, petrified manzanita knot and jaspers; case containing antimony, asbestos, fire clay, calcite, serpentine, diabase, porphyry, gypsum, quartz, crystals and amethysts; case of specimens containing free gold, sheet gold, nuggets, placer gold, river gold and gold dust.

Sierra County.—The most prominent feature of the Sierra county exhibit is the great gilded obelisk, which rises from its center to a height of twenty or more feet, and which is designed to represent the bulk of the county's gold output since the discovery of gold. The weight of the output is stated to be 596,000 pounds; cubic contents, 535 feet; value, \$180,000,000. It is a popular thing among the various counties to afford in this manner, by actual demonstration, a conception of the value of the resources. The representations are in various forms of the one general idea, and it is not too much to say that Sierra is one of the most happy of all. The display as a whole is unpretentious, the chief object being to show the average character of the county's milling ores in virgin form. This

aim has been completely accomplished, quartz from twenty different mines under development being displayed, as well as river, placer and drift gravel. The exhibit is not bulky, but the varieties of ore, from free-milling to sulphuretted and "pocketty," are adequately shown. From one mine—the Empire, in Gold Valley—unique specimens of sulphuretted rock are shown, the rock being completely hidden by the sulphurets. The leading mine of the county, the Gold Bluff, is represented by views of its surface works and its various officers, as well as by quartz. Fac-similes of gold brick and amalgam balls before retorting are also shown. If the display is wanting in any respect it is in gravels, of which but few specimens are to be seen. These, however, are very good.

It is intended to place on exhibition soon a paraffine cast of Sierra county topographically, giving an idea of its mountains, its geologic formations and the location of its different mines and mining districts. This will, no doubt, be a valuable contribution to the exhibit. Mr. Robert Forbes is in charge.

The Sierra county exhibit, as a whole, is as follows:

Gold ore from the William Tell mine in the Sierra City district; gold ore from the Gold Bluff mine of the Downville district; gold ore from the Empire mine in the Gold Valley district; gold ore from the Mountain mine in the Sierra City district; gold ore from the Young America mine in the Sierra City district; gold ore from the Oxford mine in the Downville district; gold ore from the Nip and Tack mine in the Downville district; gold ore from the Phoenix mine; gold ore from the Butte extension mine in the Sierra City district; gold ore from the High Commissioner mine; gold ore from the Butte Saddle mine in the Sierra City district; gold ore from the Independence mine in the Wolf Creek district; gold ore from the Mexican mine in the Downville district; gold ore from the Sacred Monnd mine in the Sierra City district; gold ore from the Milton mine in the Sierra City district; gold and copper ore from the Pride mine in the Sierra City district; ribbon quartz from the Gold Bluff mine in the Downville district; gold-bearing gravel from the Downville mine in the Downville district; gold-bearing gravel from the Bald Mountain extension in the Forest district; gold-bearing gravel from the Wide Awake mine in the Downville district; marble from the Sierra quarry.

Slitkens.

The Montana output of copper for last year was 150,092,711 pounds; for Michigan, 113,462,129 pounds; for Arizona, 43,717,425 pounds.

The Purdy Gold Mining Company has been incorporated in San Francisco. Directors—H. C. Gilbert, O. A. Poage, H. L. Gilbert, H. W. Snow and I. L. Gilbert. Capital stock, \$1,000,000.

The Lethbridge, B. C., coal-miners' strike did not last long. When the men found that their places could be supplied they made concessions, which were received, and the men returned to work.

The Sunrise Gold Quartz Mining Company has been incorporated in San Francisco. Directors—E. H. Baxter, George F. Hill, D. J. Halloran, E. F. Baxter and James P. Sweeney. Capital stock, \$1,000,000.

MELVILLE ATWOOD, M. E., has received a letter from S. P. Dorsey, principal owner of the Maryland mine, in which it is stated that the pay chute had been reached on the 1600-foot level when the fire occurred. The ledge is eight feet wide. Operations will be resumed in about ten days.

The Tacoma smelter shipped 1600 bars of bullion, weighing 175,457 pounds and valued at \$36,296.12, during February. There were 1063.66 ounces of gold, valued at \$21,895.85; silver 14,196.98 ounces, valued at \$816.32; lead, 174,417 pounds, valued at \$5493.95. Fifty-eight men were on the payroll and \$3437.80 disbursed.

FARMERS on river bottoms are getting impatient with so much dampness, but the placer miners are all happy, says the *Rogue River Courier*. The rain keeps the farmers shut in the house when they think they ought to be at work in the field; but the more Jupiter Pluvius turns the bottom of his pitcher up, the more the placer men smile, as they wash away the red banks and uncover the glittering nuggets.

FRANK HOBBERO and George V. Holcomb are advertised by local papers as having engaged in questionable mining transactions in southern Oregon and Siskiyou county, Cal. They bonded mines right and left and never paid a cent. Holcomb, after putting up a mill in Siskiyou he had obtained from Jackson county, Or., on a mine he had bonded, levanted, leaving 15 employees and various other victims in the lurch.

CAPT. J. R. DE LAMAR, the well-known mining man, is in the city accompanied by his wife. Mr. de Lamar has achieved the doubtful distinction of being written up in the local press as the Monte Cristo of the West, who, five years ago, was a poor sailor, went to Idaho, found a mine worth millions, and has now married one of the 400 and is on his way around the world with the evident intention of taking possession of it.

The Poorman mine, the property of the Cœur d'Alene Silver and Lead Mining Company in the Cœur d'Alene district, Idaho, has been sold to English capitalists for \$500,000, of which \$100,000 is to be paid down and the balance in two equal payments at six and twelve months. The property is one of the greatest lead producers in the country, and for the past six years has paid dividends regularly until the last three or four months, when it has been worked only sufficiently to pay expenses.

The syndicate of Denver capitalists who took a bond on the Mercut gold mine in the Camp Floyd district, Utah, for \$750,000, have obtained another extension until April. It is stated that the reason is that the Colorado capitalists who have the bond from the Mercut company, are selling the mine to a company of Eastern capitalists for \$1,500,000. The Colorado capitalists are all satisfied with the mine, but the Eastern company will not take the report of their experts and are having the mine thoroughly experted.

The placing of coal on the free list in the United States will not have any appreciable effect upon our trade with that coun-

try, except so far as the cheapening of the article may encourage increased consumption, remarks the *Australian Mining Standard*. Those who are anxious to see our coal trade expand should gladly welcome any movement in the direction of freeing the markets of the world, and though it is too much to expect that any direct advantage will be felt by our coal-owners, the circumstance referred to is an encouraging one.

The DeLaval process of electrical extraction of metal from the ore is being practically applied at Trollhattan, Sweden, where a waterfall has been secured for the purpose. The experiments have hitherto been confined to Granesburg ore, but will, it is understood, soon be extended to the iron ore from the vast deposits in north Sweden. It is expected in some quarters that DeLaval's invention will revolutionize the Swedish iron industry. The process is said to be both simple and cheap when water power is available, and is already attracting much attention.

W. M. GWIN, shipping commissioner of San Francisco and owner of the famous Gwin mine in Calaveras county near Middle Ber, has executed a bond of that property to F. F. Thomas, formerly superintendent of the Kennedy mine. The new company with Mr. Thomas at its head means business, and already Knight & Co. of Sutter Creek are figuring upon hoisting machinery capable of sinking 2000 feet. It will be run either by water or by electricity with auxiliary steam connections to be used in case of failure of water. The company hopes to be able to commence work by the first of April.

The Potosi Mining Company has elected the following officers for the coming year: A. K. P. Harmon, president; Thos. Cole, vice-president; and Thos. Anderson, E. P. Berrett and D. C. Bates, directors. C. E. Elliot was re-elected secretary, and his financial statement showed a credit of \$1059.08. The annual bullion statement was as follows: Total production, \$294,732.20; of this, \$88,342.10 was in gold and \$206,390.10 in silver. The discount was 28 per cent, or \$83,097.79. Net returns, \$211,634.41, less cost of milling, \$91,849.35. Net returns over cost of milling, \$119,785.06. H. H. Gorham was elected superintendent, vice A. C. Hamilton, resigned.

The Colorado smelters have issued a new scale of prices, to which sulphur and silica penalties are attached. Twenty-five cents will be charged when the ore contains from 3 to 12 per cent of sulphur, and \$3 per ton will be added to the treatment charges when the sulphur reaches 12½ per cent. Silica will be charged for at the rate of 15 cents for each per cent in excess of iron. It is claimed that other changes will be made in the rates that will equalize the total, and make the smelting charges no greater than they have been heretofore. This offers an opportunity to the miners to study the composition of their ores, and do a little mixing to avoid penalties.

A. L. HOLMES, of this city, has just returned from the Four-mile placer gold mining district of Wyoming. "The 'burial process' is being introduced there for saving fine gold, and it is thought to be a great success," said he. "If such proves to be the case, that district will make one of the richest placer fields in the West, there being a scope of country, 30 miles wide by 40 or 45 miles long, that carries gold in the sand from the grass-roots to the bedrock, which in some instances is 18 feet below the surface. One peculiarity of the gold find is that, while some of it is very fine, it is not what is known as flake or flour gold, but under the glass it shows up distinctly of a lumpy nature."

The Oroville *Mercury* considers the mining outlook in that county very promising. "In the last year," says the *Mercury*, "hundreds of new ledges have been discovered, located and prospected, and it would now appear that only a beginning has been made. Many of these ledges are owned by poor men who will sell at reasonable figures. Mining in this line is not conducted as it once was, haphazard and ignorantly, but it is conducted scientifically. The gold has always been there, only in the past miners did not know how to save it. The best example of this is the Forbestown district. Although the hills there for years were known to be ribbed with gold-bearing quartz, every attempt to work the same resulted in failure. Under the new order of things, every one of those ledges has been made to pay."

The celebrated McBride case is again before the department at Washington. It is one of the most important cases ever brought there, the controversy having arisen over an application for a mineral placer claim valued at between \$3,000,000 and \$4,000,000. There were six locations, each covering 20 acres, on claims made by right of discovery in September, 1889, by M. Topliff, G. P. Topliff, Reed O. McLean, F. T. Crowe, H. R. Laplain and H. O. Leiger, who subsequently sold the claim to McBride. The attorney-general of the State filed a protest against the application, alleging that all the section on which entry was sought is State property; that the land contained no valuable mineral deposits, but was wanted as city property, as it joins Tacoma (wherein its real value lies), while McBride asserted that gold existed in paying quantities, entitling him to the property. Secretary Smith held that a hearing would be necessary to determine the value and extent of the alleged deposits and ordered thorough prospecting of the land. A special agent of the department will be present at this investigation and the case has been made special to secure an early settlement.

The Congress mine, near Prescott, Arizona, which was recently sold to an English syndicate for \$1,000,000 (so the amount is given) belonged to the estate of "Diamond Joe" Reynolds, who was well known on this coast and in San Francisco in particular. He bought the mine for \$1800 from a prospector, and it was worked four years, but shut down when he died. "Diamond Joe" was for many years a cook on the Mississippi river, but eventually became the possessor of a large fleet of freight boats, plying between St. Louis and St. Paul. He was also a heavy investor in Arkansas property, particularly in Hot Springs, and he built the line of railroad running from Malvern Junction, four miles below Little Rock and at the intersection of the Iron Mountain road, to Hot Springs. The road was for many years the only means of entry to Hot Springs and was a source of huge income, being only twenty miles long and the fare between the two points being \$2. He gained his peculiar title because of the large and valuable diamonds which he always wore, and he utilized it also as a trademark, all his steamers being ornamented on each side with the word "Joe" in a white space of diamond shape.

The Colorado Troubles.

Colorado has been the scene of a vast tumult and excitement during the past ten days. A great deal of gory talk has been indulged in, but so far nothing but words have been shed. The situation has now quieted down, and it seems probable that the difficulties which gave rise to the troubles will be amicably adjusted. Denver politics and Governor Waite's contumacy were the origin of the first part of the row, which need not be discussed here. The second arose from the mining troubles at Cripple Creek. The strike of the miners had continued for several weeks without settlement, or prospect thereof; and the mine-owners resolved to take the bull by the horns and start up anyway.

The mine-owners decided upon two propositions, either one of which the miners could accept, and under either system any mine might be started up. The wages offered were \$3 per day for a shift of 9 hours with 30 minutes out for lunch; or \$2.50 per day where 8-hour shifts are worked, with 30 minutes out for lunch. This gave the miners an option and also the mine-owners. Those mines sufficiently developed to work three 8-hour shifts could adopt the 8-hour plan, while those properties not so far developed could adhere to the 9-hour shift. Judge Downer, of the district court of El Paso county, issued an order enjoining the Miners' Unions not to interfere in any way or molest the men who desire to go to work.

Under this plan the Anaconda, Victor, Anna Lee, Summit, Isabella, Strong, Gold King, Gold Dollar, Zenobis, Pharmacist, and others, started up. The Miners' Union determined to break up this arrangement, and armed themselves. The sheriff swore in a large number of deputies to preserve the peace and protect the non-union miners. A conflict ensued, at Altman, and one deputy was shot. The whole region became tremendously excited. The militia was ordered out. Then the district came to its senses. No one really wanted to fight. The miners did not care to antagonize the organized National Guard, and the latter certainly had no overpowering desire to fire on the miners. So the peaceable method of settlement was taken because it was the easiest, most law-abiding and likely to be the most satisfactory.

It seems probable now that the whole difficulty will be adjusted on substantially the terms offered by the employers, as indicated above. These terms are in reality a concession to the demands of the miners. The mine-owners wanted to pay \$3 for nine hours' work; the miners wanted \$3 for eight hours' work. The Independence, one of the largest mines, has started work again with a small force on the basis of nine hours for the day shift and eight for the night shift, miners to receive \$3.25 per shift. This offer was made the day the men quit work several weeks ago and refused. It was renewed a few weeks ago and is now accepted by the Miners' Union. This may be taken as an indication that the union is now prepared to meet the owners half way. The Cripple Creek camp will probably be active again at a very early day.

The Bland Seigniorage Bill.

The Bland bill for coining the silver seigniorage and other bullion, which now awaits President Cleveland's signature, provides as follows:

SECTION 1. That the Secretary of the Treasury shall immediately cause to be coined as fast as possible the silver bullion held in the Treasury purchased under the act of July 14, 1890, entitled "An act directing the purchase of silver bullion and the issuing of Treasury notes thereon, and for other purposes," to the amount of the gain or seigniorage of such bullion, to wit: The sum of \$55,156,681, and such coin of the silver certificates issued thereon shall be used in the payment of public expenditures, and the Secretary of the Treasury may, in his discretion, if the needs of the Treasury demand it, issue silver certificates in excess of such coinage; provided, that said excess shall not exceed the amount of the seigniorage as herein authorized to be coined.

SEC. 2. After the coinage provided for in the first section of this act, the remainder of the silver bullion purchased of said act of July 14, 1890, shall be coined into legal tender standard silver dollars as fast as possible, and the coin shall be held in the treasury for the redemption of the Treasury notes issued in the purchase of said bullion; that as fast as the bullion shall be coined for the redemption of said notes the notes shall not be reissued, but shall be canceled and destroyed in amounts equal to the coin held at any time in the Treasury derived from the coinage herein provided for, and silver certificates shall be issued on such coin in the manner now provided by law; provided, that this act shall not be construed to change existing law relating to the legal tender character or mode of redemption of the Treasury notes issued under said act of July 14, 1890. That a sufficient sum of money is hereby appropriated to carry into effect the provisions of this act.

ARTICLES of incorporation have been filed in this city by the Consolidated Copper and Quicksilver Mining Company. The purpose of said corporation is to buy and sell copper and quicksilver mining claims, etc. Capital stock \$1,000,000, of which \$50,000 have been subscribed. Richard Phelan has subscribed \$10,000; J. T. Wilson, \$10,000; Fred Gottfried, \$10,000; R. M. Spencer, \$10,000; Albert Bachman, \$10,000.

Hard Times and Good Prospects.

TO THE EDITOR:—Business is dull in San Francisco. It is more or less so in other places, but other places make some effort to remedy the trouble. They don't sit down in sackcloth and ashes and mourn, nor did San Francisco in times past. It remains for the present generation of California and their companions, the late arrivals, to do most of the weeping and wailing. They have concentrated their wealth, energy and enterprise in and around San Francisco, and have got their business into a sort of pot hole and can't get it out. They dare not trust their capital beyond the corporate limits of the city and county, and hardly there. In olden times, when business was dull in the city and there was a surplus of labor, the crowd would rush to the mines, where they were pretty certain to make a living if not to make a big strike. Let those of the present population, who can, do the same, but in a slightly different way. They are not all miners, nor do many of them wish to become working miners. It is not necessary that they should; but they can become interested in mines, and furnish the money to open them so that our surplus labor can be employed.

The times are favorable for the development of our California gravel and quartz gold mines, there being plenty of unemployed miners ready and willing to work at reasonable wages, and the mining industry seems to offer a better field for the investment of capital than any other industry at present. Along the western slope and summit of the Sierra Nevadas, from the Mexican to the Oregon line, within our State, are innumerable gold-bearing gravel beds and quartz veins, large and small, showing gold in fair quantities. Many of these have been worked for a generation, supporting the owners and their families, perhaps not in the height of luxury, but often comfortably. On most of the quartz veins but slight depth has been attained, owing to the lack of sufficient money for their proper development. Interests in these mines or prospects can be secured, or they can be purchased at low prices, and are sufficiently promising and extensive to warrant the formation of companies or partnerships to furnish the necessary capital to prosecute further work, with a great degree of profit to the investors.

What better use could much of the idle capital of San Francisco be put to, and what better chance is there for making money than in opening up some of those or similar mines? San Francisco has been sending coin by the million to Nevada and other neighboring States and Territories to pay for the development of mines. Far-off hills have always looked the greenest to San Franciscans, while she has neglected just as good and many better and easier opened prospects and mines at home. If but a small percentage of the possibly good mines of this State were opened, or were now in course of development, there would be fewer unemployed men in this city and much better times throughout the State. In San Francisco the provision dealers would be furnishing the necessary supplies to the mines and miners. The foundries and machine shops would be working overtime. All other industries would be flourishing and prosperous and the people happy instead of poor and discontented. The merchants and manufacturers have lost much of the trade with adjoining States and have done next to nothing to encourage their own State mining industry, when by doing so they would have created new demands for their goods and ensured prosperity in business for themselves.

Where mining, either in gravel or quartz, has been conducted with honesty, economy and determination, with common sense added, it has been reasonably successful—as much so as farming, orchard or vineyard enterprises. Mining in California produces, under unfavorable circumstances, over \$10,000,000 per annum, and has been the only really profitable industry that California has known. It is capable of indefinite extension and can be made so as to employ all the men who can be induced to come to the State, if our own people will furnish the money necessary for a good start in developments. The field is large and can be worked profitably—I don't mean the Panzer alley or Pine street kind of mining, a kind that has done more to injure legitimate mining than has anything else. What I mean is actual, honestly conducted mining for gold—a product which finds a ready market and is not affected by overproduction, high freight or tariff reform.

If our capitalists, property owners, manufacturers and merchants wish to see the population drift away from our city and State, the value of their lands depreciate, their buildings vacant and the few remaining manufactories closed, a good way to bring about such a result is for them to keep their money in San Francisco, so they can see it all the time; and some of them can live on the rents or interest paid, others on their profits from wheat, fruit and vine—when they pay. Let them fossilize, so to speak, while the mining wealth of our State remains for wiser and more enterprising men to develop, and for a broader-minded generation to enjoy. It would, however, be much better

for themselves and for all hands if our capitalists, great and small, would wake up, brush the cobwebs from before their eyes, and lend a helping hand in the development of our mines. By so doing, the reality they now possess would increase in value, population would crowd to our State, as in days gone by, trade would be brisk, and California regain her reputation for push, enterprise and prosperity. It would be much more reasonable to contribute capital for the employment of labor to prospect and open up paying gold mines, safer and more creditable to our State, than is now being done in giving money to pay the "unemployed" for doing work which brings no profit and develops paupers.

Let those who cannot go to the mines, as in the olden times, invest a portion of their money in them, or, in other words, "put up" for the expenses and send partners or substitutes they can trust to do the work, while they themselves enjoy much of the profits.

Remember that the greatest part of all the gold that is taken out of our mines comes to San Francisco.

SCRATCH G. RAVEL.

San Francisco, March 20, 1894.

Work in the Slocan District.

The principal mines of the Slocan country, 15 in number, now give employment to about 250 men and they are taking out 100 tons of high-grade ore per day, according to a recent estimate in the Kootenai Herald. A correspondent of that paper, who has carefully compiled his data, believes that there is a similar number doing assessment work and developing smaller properties. He furnishes data of the work of the biggest claims, from which the following is taken:

	No. Employees.	Ounces Silver.	Per cent Lead.
Slocan Star.....	20	120	65
Noble Five.....	54	200
Washington.....	45	155	70
Mountain Chief.....	21	130	70
Dardanelles.....	20	300	28
Antelope.....	5	100	50
Freddie Lee.....	23	160
Northern Belle.....	25	160	60
Surprise.....	12	229
Blue Bird.....	10	144	71

The Slocan Star, it is claimed, has a contract with the Canadian Pacific railway to furnish 500 tons of ore, which is now being stored at Three Forks. The Noble Five expects to have 1000 tons on the market before the sleigh road breaks up. The Mountain Chief is storing ore at Three Forks, to await the coming of the railroad. The Dardanelles and Antelope are shipping ore to Tacoma. The Freddie Lee is shipping to Montana. In all, it is estimated, 4000 tons, valued at \$600,000, have been shipped since the discovery of the camp.

The South African Situation.

Extract from a Private Letter to a Mining Man in Seattle.

JOHANNESBURG, South Africa, January 22, 1894.—I will write you a few lines to let you know I am still alive. I am foreman in a mine. My pay is \$75 per month; board, \$25 per month, without bed. This is no country for a white man. Negroes do all the hammer and drill work. Their pay is 62 cents per day. There are 50,000 of them working within thirty square miles of here. There are 1500 stamp mills in one line of fifty miles. Each mill has from ten to one hundred stamps. The rock is low grade, assaying from \$3 to \$15 per ton. It is sulphurets and requires the McArdie process. The ledges have been prospected by diamond drill 2000 feet deep, and the rock is the same all the way down. This is a prairie country. The soil is red sand, and very poor. It will not produce without water. The Dutch Boers are an ignorant, lazy people. There are between 70,000 and 80,000 of them in the Transvaal republic. The negroes are worth nothing here. You can buy a good strong buck for \$100.

I will leave this country as soon as I can earn money enough to get away. There are a great many American miners here out of employment. Africa is no place for a tradesman or laborer.

T. R. BRAZILL

ANY abandoned lode, vein or strata claim may be relocated, and such relocation shall be prospected by sinking a new discovery shaft and fixing new boundaries in the same manner as provided for the location of a new claim; or the locator may sink the original discovery shaft ten feet deeper than it was at the time of its abandonment, and erect new or adopt the old boundaries, renewing the posts if removed or destroyed. In either event, a new location stake shall be fixed. The location certificate of an abandoned claim may state that the whole or any part of the new location is located as an abandoned claim.

The Red Point Drift Gravel Mine.*

By C. F. Hoffmann, Mem. Tech. Soc'y.

In Three Parts.—Part III.

DISCUSSION.

Before reading the paper Mr. Browne said:

The drift mine of which Mr. Hoffmann's paper treats, is in one of the ancient river beds of the westerly flank of the Sierra Nevada. These are found in a striking topographical position, occupying the summits of the modern ridges, high above the present streams. This apparently anomalous position is due to the displacement of the ancient streams by lava and mud flows from volcanic eruptions in the high Sierra. These flows filled the old river beds and diverted the streams, which cut new beds to gradually greater and greater depths, leaving eventually portions of the gravels of the ancient rivers, with their volcanic caps, to form the modern ridges, as shown in the following cross section (Fig. 2).

The gold is contained mostly in the bottom layer of gravel under the volcanic cap. The method of mining is by driving a tunnel in from the hillside to tap the bed and drain off the water, and to serve as a tramway for delivery to the surface. The auriferous gravel is excavated, carried to the surface, and dumped on to a sloping floor at the mouth of the tunnel, and washed thence through a line of sluices, provided with riffles to catch the loose particles of gold—the gold dust.

Much of the data furnished by Mr. Hoffmann cannot be found in a published form, and is of special value to engineers in making estimates for similar enterprises.

After reading the paper Mr. Browne added: Aside from the figures giving working results, Mr. Hoffmann has observed several occurrences which I have not heretofore heard described, and which appear to me as having special interest. These are particularly: the poverty of the gravel where the boulders are coated with microscopic crystals of quartz; the effect of the strike of the natural riffles relatively to the course of the river in determining the position of the pay streak; and the greater the purity of the gold where large quantities of percolating water were encountered in the gravel breast.

This latter observation indicates that the gold particles have undergone a slow process of purification by prolonged washing.

There is no doubt in the minds of those most familiar with the occurrence of auriferous gravels that the gold dust was derived from the degradation of the gold-bearing quartz veins. But it is a matter of common information that the placer gold is purer than the gold in the quartz veins, and this fact gave rise to disputes concerning its origin. It was asserted by some theorists that the greater purity showed a difference in origin. However, the evidences of the derivation of the placer gold from the quartz veins are conclusive, and it remains only to explain the greater purity. I have for some time past been collecting information on this subject, and find the following averages from a large number of our California mines: Gold taken from placers, .890 fine; from quartz veins, .820 fine. The other constituents are mainly silver, partly baser metals.

The theory has been advanced that the silver and baser constituents when exposed to the action of the air and water are partially oxidized and dissolved, while the gold remains unaltered. In this way there results a purification of the outer film. The aggregate effect on the fine particles would be greater than on the large nuggets, and in fact the greater purity of the fine dust and of the outer films of nuggets is well known to dealers in placer gold.

Mr. Hoffmann tells me that, in the Red Point mine, in passing from a comparatively dry into a very wet section the purity of the gold dust always increases, generally from

.003 to .005, or say one-half per cent. Though something of the sort might have been anticipated, it is the first time I have heard of its being actually observed.

MR. MANSON.—Aside from the technical interest that the mining engineer would take in this paper, there is a great deal in it and in Mr. Browne's explanation of the occurrence of these two sets of river channels and the obliteration of one set with the lava overflow that interests the geologists.

I have had occasion to examine the western slope of the Sierras from a few dozen miles south of the point so interestingly described in this paper, to Mt. Shasta, and the western slope of the Rocky mountains in eastern Washington, Idaho and Montana. In that area, embracing parts of California, Washington, Oregon, Idaho and Montana, there are about 150,000 square miles, which are or have been covered with lava. Toward the northern edge, up in Montana, Idaho and Washington, the lava is from half a mile to a mile and a half thick, and is of dense basalt. Toward the southern edge or limit it appears to have degenerated, or certainly decreased in hardness as well as in thickness, and in some instances it is a mud lava that can be picked and handled without any very great trouble. In the Sierras the first set of river channels appears to have been formed during the period of denudation that followed that upheaval.

The denudation of portions of the Sierras amounts to about two miles in thickness, and in some instances to more. As that two miles was denuded from the western slopes of the Sierras, which was a line of lighter crust in process of upheaval, the amount of denudation lightened the load upon the crust and destroyed the state of isostatic equilibrium that the crust is always in. This caused the crust to upheave more. The denuded materials transported down the sides of the Sierras by water and gravity were deposited in the great valley of California, and this already in process of sinking was more heavily loaded. The additional load on the sinking area caused it to settle still farther; so that denudation acted in a double way to accentuate the difference of elevation between the valley and the mountains—that is, the continuous denuding of the one caused the building up of the other. At the same time, the process caused the valley to settle more and the mountains to upheave to a greater extent. Toward the latter part of the Tertiary, and probably running well into the Quaternary period, the process of denudation seems to have been interrupted by this lava flow, as Mr. Browne described, and a new set of river channels started in. In most instances these ran across the others, and in the modern rivers the richest deposits have been found just below where they had cut through the ancient river channels, the gold in the modern channels being the result of a double set of concentrations, first in the denudation and filling up of the ancient river channels, and finally in being reconcentrated in the modern rivers, leaving the enormously rich deposits that the forty-niners worked with such good results.

I regard this paper as an exceedingly valuable one, because it describes mining as a business enterprise. Mining in the early days, and even up to 1877, was largely a gambling operation; after the mine was located, the stock was put on the market, and it made but little difference whether the mine was valuable or not. So the mines were not systematically worked, and in many of the old river channels there are wonderful deposits yet; and I believe that the mining engineer and the geologist have before them a field of wonderful fertility in following up these river channels not only in the high Sierras, where they are covered by the lava caps, but by following them down into the plains below the level of the present alluvial surface of the valleys and also in the drift mines well under the surface of the present rivers. And I believe that this is going to be a line of mining which will be followed very largely in this country, and that projects of this nature will ultimately prove very attractive to capitalists.

MR. STRIEDINGER.—Mr. Hoffmann's paper fills, in a masterly manner, a long-felt gap in the literature on gravel mining. How thoroughly and economically the exploitation of the Red Point drift mine is carried on under his superintendence is shown by this abstract from his reports.

Mr. Browne has not mentioned the fact that he and Mr. Hoffmann executed the original survey of this mine, and subsequently located the tunnel, which, by crossing the ancient river channel about 20 feet below its deepest point, causes a perfect drainage of the underground workings. There are very few drift mines which are so well laid out.

Drift mines are not confined to the Pacific Slope of our Sierra. Not quite a year ago I discovered some drift

mines on the westerly foothills of the Andes, near Barbaçoas, Republic of Colombia, S. A. Drier drift mines than the "Red Point" are usually opened by means of inclined shafts with drifts extending from their bottoms.

MR. BROWNE.—The deep drain tunnel is necessitated by the amount of water contained in the channel. In the Red Point this amounts to 35 or 40 miner's inches, in the Mountain Gate and Hidden Treasure to 40 inches each, in the Mayflower, farther down the ridge, to 75 inches. If mined through deep shafts the handling of such quantities of water would eat up the profits.

There are a series of drift mines in the Harmony ridge, near Nevada City, however, where the gravel is almost dry, and the work there is most profitably carried on, as stated by Mr. Striedinger, through inclined shafts. The advantage of the inclined shaft is that it is shorter, and it may be run down on the rim rock until the bottom is reached, and it is not necessary to rely upon a vague estimate of the depth or position of the channel bed, as might be the case in driving a tunnel. But it should be borne in mind that every miner's inch means about 70 tons of water per 24 hours, and that the expense of lifting a very few inches will often amount to more than the expense of hoisting the total amount of gravel extracted. For example, the Mayflower mine delivers about 140 tons of gravel per day, and there runs through its drain tunnel nearly 40 times this weight of water.

Side Lines and End Lines.

The text of the decision of the United States Supreme Court in the case of *Silas F. King vs. the Amy & Silver-smith Consolidated Mining Company*, on appeal from the Montana Supreme Court, has been received. The opinion of the court is by Justice Field. It is of much importance, and it is herewith given practically in full.

The plaintiff and defendants are owners, as tenants in common, of certain mining property in Silver Bow county, State of Montana, known as the Non-consolidated lode mining claim. The plaintiff owns three-fourths of the claim and the defendant one-fourth. The defendant is, besides, the sole owner of the mining claim situated in the same county and State, known as the Amy lode mining claim. Both claims are located and patented under the mining laws of the United States contained in Sections 2320 and 2322 of the Revised Statutes. The Amy claim was first located and has the earlier patent.

The relative positions of these two claims are seen on the diagram in the record, which shows the course of the vein in the Amy claim upon which its location was made and the boundaries of the two claims, with the length and direction of each. The description of the two claims can be understood only by reference to the diagram, as each line is given. A copy of the diagram is here produced, as without it the description will be unintelligible to the reader.

DIAGRAM OF THE AMY AND NON-CONSOLIDATED CLAIMS.

The Amy claim has a surface length of 1470 feet, and its side-lines are parallel. The end-lines are each 491 feet, and they are also parallel. The surface location forms a parallelogram of 1470 feet running easterly and westerly, by 491 feet running northerly and southerly.

The Non-consolidated claim lies adjoining the northwest corner of the Amy claim. Its surface shape is that of a triangle, the longest side of which joins the northerly side of the Amy claim, and, commencing 17 feet from the northwest corner of the latter, extends easterly 411 feet in length. Its northerly side-line, commencing (on the northerly line of the Amy) at the point where the first line terminates, runs in a northwesterly direction 372 feet to the point where it meets the westerly line of the lode, and extends southwesterly from this point 181 feet to the place of beginning.

The vein of the Amy claim, on its course or strike, passes through its northerly side-line, as marked on the diagram, into the Non-consolidated ground; its apex crosses that line 184 feet easterly from the west side-line of that claim, and does not again enter the Amy claim. The apex of the vein enters the south side of the Amy claim at a point within 600 feet westerly from the southeast corner of the Amy, and the dip of the vein is to the north.

The plaintiff has brought this action for a partition of the

*The accompanying paper, of which an abstract was printed in the Press on Jan. 13, 1894, is a most important contribution to literature on the subject of drift mining. In response to numerous inquiries, and by permission of the Technical Society of the Pacific Coast (before which the paper was read), the full text is given.

Non-consolidated claim with the defendant, according to the respective rights of the parties, if that be possible; but if the property cannot be thus partitioned advantageously, then for a sale of the premises and a division of the proceeds among the owners, in conformity with such rights.

As stated above, the vein of the Amy, of which the apex lies within the surface lines of the claim, in its course passes through the northerly side-line, and enters the Non-consolidated claim; and it is alleged that the vein has been there worked by the owners of that claim and valuable ore taken therefrom. The plaintiff, therefore, prays, in addition to a partition or sale of the Non-consolidated claim, for an accounting for his share, as tenant in common of an undivided three-fourths of that claim, of the ores taken from the underground workings of the vein of the Amy after it had passed into that claim, if any there were.

The defendant admits co-tenancy in the Non-consolidated claim with the plaintiff, but denies the taking of any ore from the vein of the Amy after it had passed into its ground.

The first question for determination is whether the Amy retained any right to the vein, the apex of which was within its surface lines, after it had passed through its northerly side-line, or, rather, through the vertical plane running down that line. If the Amy retained its right to that vein after it had entered the ground of the Non-consolidated claim, it belonged to the defendant as sole owner of the Amy, and he could not be called on to account to the plaintiff for any portion of the ores taken from it. If, on the other hand, the Amy did not retain its right to that portion of the vein after it had passed into the Non-consolidated claim, it became a part of that claim, and the proceeds of the ore there taken from it would, with other proceeds of the Non-consolidated claim, be the subject of an accounting between the plaintiff and the defendant, the owners, as tenants in common of that claim. The answer to the question must be found in the construction given to Section 2322 of the Revised Statutes, which took effect December 1, 1873, and which provides that locators "shall have the exclusive right of possession and enjoyment of all the surfaces included within the lines of their locations, and of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of such surface locations. But their right of possession to such outside parts of such veins or ledges shall be confined to such portions thereof as lie between vertical planes drawn downward as above described, through the end lines of their locations, so continued in their own direction that such planes will intersect such exterior parts of such veins or ledges."

The preceding section (2320) prescribes the extent to which mining claims upon veins or lodes of quartz, or other rock in place, bearing gold, silver or other valuable deposits on lands of the United States, may be taken up after May 10, 1872. It allows a claim to be located to the extent of 1500 feet along the vein or lode, but provides that no location shall be made until the discovery of the vein or lode within the limits of the claim located, which is, in effect, a declaration that locations resting simply upon a conjectural or imaginary existence of a vein or lode within their limits shall not be permitted. A location can only rest upon an actual discovery of the vein or lode. The section also declares that no claim shall extend more than 300 feet on each side of the middle of the vein at the surface; nor shall any claim be limited by any mining regulation to less than 25 feet on each side of the middle of the vein at its surface except as prevented by adverse rights existing on May 10, 1872, and that the end-lines of each claim shall be parallel to each other. A claim located in conformity with the provisions of this section would take the form of a parallelogram, if the course or strike of the vein or lode should run in a straight line; but such veins and lodes are often found upon explorations to run in a course deviating at different points from such line. And from this circumstance much difficulty often arises in determining the lateral rights of the locators.

Section 2324 of the Revised Statutes recognizes the power of miners in each mining district to make regulations not in conflict with the laws of the United States, or of the laws of the State or Territory in which the district is situated, governlog the location, manner of locating and amount of work necessary to hold possession of a mining claim, subject to the requirement that the location must be distinctly marked on the ground so that its boundaries may be readily traced. It is evident from the provision cited that the location as made and defined must control not only the rights of the claimant to the vein or lode within its surface lines, but also any lateral rights.

Section 2322, cited above, declares that the locators of all mining locations shall have the exclusive right of pos-

session and enjoyment of all the surface included within the lines of their location; and also the exclusive right of possession and enjoyment of all veins, lodes and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of said surface location. The surface side-lines, extended downward vertically, therefore determine the extent of the claim, except when in its descent the vein passes outside of them, and the outside portions are to lie between vertical planes drawn downward through the end-lines.

The difficulty in the present case arises from the course of the vein or lode upon which the Amy location was made. It is evident that what are called side-lines of the location, as shown in the diagram, are not such in fact but are end-lines. Side-lines, properly drawn, would run on each side of the course of the vein or lode, distant not more than 300 feet from the middle of such vein. In the Amy claim, the lines marked as side-lines cross the course of the strike of the vein and do not run parallel with it. They, therefore, constitute end-lines. It is true the lines are not drawn with the strict care and accuracy contemplated by the statute, and which could only have been done with more perfect knowledge of the true course or strike of the vein from further developments. But, as was said by this court in *Iron Silver Mining Company vs. Elgin Mining Company* (118 U. S. 196, 207): "If the first locator will not or cannot make the explorations necessary to ascertain the true course of the vein, and draws his end-lines ignorantly, he must bear the consequences." The court cannot become a locator for the mining claimant and do for him what he alone should do for himself. The most that the court can do, where lines are drawn inaccurately or irregularly, is to give to the miner such rights as his imperfect location warrants under the statute. It cannot relocate his claim and make new side-lines or end-lines. Where it finds, as in this case, that what are called side-lines are in fact end-lines, the court, in determining his lateral rights, will treat such side-lines as end-lines and such end-lines as side-lines; but the court cannot make a new location for him, and thereby enlarge his rights. He must stand upon his own location, and can take only what it will give him under the law.

Acting upon this principle there is no lateral right to the holder of the Amy claim by which he can follow its vein into the Consolidated claim. Mistakes in drawing the lines of a location can only be avoided, as said in the case cited, by postponing the marking of the boundaries until sufficient explorations are made to ascertain as near as possible the course and direction of the vein. "Even then," the court added, "with all the care possible, the end-lines marked on the surface will often vary greatly from a right angle to the true course of the vein, but, whatever inconvenience or hardship may thus happen, it is better that the boundary planes should be definitely determined by the lines of the surface location than that they should be subjected to perpetual readjustment according to subterranean developments subsequently made by mine workers. Such readjustments at every discovery of a change in the course of the vein would create great uncertainty in titles to mining claims."

Applying this doctrine to the case before us, it follows that the vein in controversy, the apex of which was within the surface lines of the Amy claim, did not carry the owner's right beyond the vertical plane drawn down through the north side-line of that claim. The Amy claim has no lateral right by virtue of the extension of the vein through what was called the north side of its claim, as that side-line, so called, was in fact one of its end-lines.

The judgment of the Supreme Court of Montana should therefore be reversed and judgment entered in favor of plaintiff for a decree of partition of the Non-consolidated claim between the parties to the suit, who are owners as tenants in common, provided such partition can be made with due regard to the respective rights of the owners; and if it cannot be thus advantageously made, that the premises be sold and the proceeds divided according to their respective rights; and further, that the respective parties render an account of the proceeds received by them, respectively, from the Non-consolidated claim, and that such proceeds be divided between them according to their respective rights.

Oregon Mining Districts.

Abridged from letter of Prof. Leigh Harnell to Portland *Oregonian*.

A great revival in our mining industry has set in earnestly, bringing with it fortunately such men and such capital as will certainly make it both profitable and permanent. I am speaking principally of placer mining in southern Oregon, where I am most familiar with the revival as it shows itself at present by an increased occupa-

tion of territory and the introduction of improved methods of working to make the occupation profitable. A person unfamiliar with the facts could scarcely realize the improvement in these respects during the last year. Take, for instance, the main South Umpqua, with Canyonville for its trading center and Riddles for its railroad center. A year ago there was not a single mining location on the river proper above Canyonville, and to-day for 30 miles it is covered with locations of great value and covering an immense area of good pay dirt on both sides of the river. By the owners of prominent locations, great efforts are being made to obtain sufficient water from the river and tributary streams for effective hydraulic mining, and these efforts will soon be accomplished. The prospect of a general remunerative pay is thoroughly established. In this section, outside the immense gravel beds in the bars and benches stretching far back from the river, all carrying gold in paying quantities, is found a large deposit of rich black sand, which in the property of the South Umpqua Mining Company assays from \$800 to \$1800 a ton, which can all be easily saved in what is called an undercurrent in mining parlance. This property is under bond to New York parties for \$100,000, and will most probably be sold next May. It will form an excellent advertisement for our State. All this new-born activity and enterprise—for it exists in every section all the way down to Jacksonville, 250 miles south—wherever possible or practicable, is cheering and hopeful to those whose lives have been spent in the dread solitude and silence of the old primeval hills.

The Olalla District.—Then, turning north from the South Umpqua river over the range of hills forming its present course, a new but extensive gold-bearing district is rapidly attracting the attention of men of means, and will be extensively prospected when spring fairly sets in. This section includes the Olalla district, where gold in paying quantities has long been known to exist, and extends north to within a few miles of Roseburg. The whole section is well watered, needing, for good work, only small and cheap ditches from one to four miles to bring water to the main gold flow. It has also the special advantage of being only $2\frac{1}{2}$ miles from the Southern Pacific Railroad—a very important advantage in the transportation of supplies and machinery to the mines. An effort was made last summer by Col. James Virtue and colleagues to get a foothold in the Olalla district, but they were vigorously opposed by a woman who refused them right of way for a ditch through her ranch, and so the enterprise fell through. The new one I now speak of, however, cannot fail, for it is free in its surroundings from all adverse action by others. The property, 640 acres, all gold-bearing, is owned by Mr. Gove, the jeweler, and a Mr. Hughes of Portland. Both are men of means and intend to bring their new enterprise to a completion as soon as possible. Thus, it is pleasant to know our revival in mining affects all classes, and that we shall soon have a new and extensive gold-bearing district, known to be rich, added to the many others which, for over 200 miles in unbroken continuity, form the wonderful placer fields of southern Oregon.

The Original Gold Flow.—From the samples of gold from this new district shown me by Mr. Gove I am satisfied it comes easily in the direct course of the original gold-flow, which forms such a conspicuous feature of southern Oregon. When once acquainted with its characteristics it cannot be mistaken. From certificates given by the San Francisco mint, the South Umpqua gold is 957 pure out of 1000 parts, and coins \$22 40 to the ounce, which is about as pure as ever taken from the earth. This is very important to prospectors in reaching final success in mining, as the coinage to the ounce makes a vital difference in different places. Before the gold-flow of southern Oregon reached its present level on the Umpqua, by the detrition of ages, there is every evidence that in earlier times it fed this new field and its surroundings as far west as Myrtle creek. Investments of capital for its development are thereby rendered safer.

But the most prominent feature of our mining revival is the introduction of a new method of washing the bars and benches of our gold-bearing rivers. This is White & Co.'s mammoth steam hydraulic plant, mentioned in a late issue of the *Oregonian*, and now on its experimental trial at Hadley's bar, two miles below Myrtle creek. Mammoth is the correct word, for it is really mammoth in construction, mammoth in operation and mammoth in success. The idea of such application for mining comes to us from Tacoma, where Messrs. White & Co. used it very successfully in washing away a large hill of dirt to make a level space needed for business purposes. On talking with Dana, Albee & Walker, of Portland, who furnished the plant for Myrtle creek, I find 40 yards of dirt 9 feet deep and 5 feet wide were washed easily in four hours' work, with a result of 50 cents a yard. Whether that is superficial or square yards matters not, for in hydraulic diggings five cents a cubic yard means a big fortune. The saving

of the fine gold, say 75 per cent, depends not so much on the amount of dirt washed as the application of under-currents to the main flume carrying off the debris.

This plant altogether cost \$5000. The economy of this method is, therefore, as remarkable as its power and success. There are few places where a ditch can be cut at \$1000 per mile, and then, if the ground should not pay, the whole investment is lost and mischief is done all round. But in this case the plant can be easily and at little expense removed to another place that will pay, and so failure finally is impossible. In any business, I imagine, such a conviction will always secure capital. This enterprise, then, marks a new era in our mining history, and is just what we needed. To show the unimpaired real power of this plant, I may say that if the volume of water it furnishes were driven through a 2½-inch nozzle against an ordinary frame building of two stories, even at 100 feet distance, it would simply demolish the entire structure in a few minutes. From this its power in mining may be justly estimated.

The F. L. Bartlett Zinc-Lead Process.*

This process is used at Canon City, Colorado, for the treatment of argentiferous zinc-lead sulphide ores. The process in general consists in separating the zinc and lead by volatilizing them in the form of a zinc-lead fume, from which a marketable pigment is obtained, while the silver is left behind with the other non-volatile metals, and is collected in a copper matte. The process is based on the fact, discovered by Dr. Bartlett, that when silver-bearing zinc sulphide ores are burned and the zinc is volatilized, the amount of silver dragged off with it is much less than was previously thought to be the case. Two methods of treating the ores are adopted according to the proportions of zinc and gangue they contain. Those containing about 25 per cent or more are treated by the first method; those containing about 22 per cent of zinc or less, by the second.

The following are examples of ores actually treated at Canon City:

	Silver.	Lead.	Zinc.	Iron.	Copper.	Silica.
1.....	10 ozs.	30 per cent.	24	38	0	5
2.....	25 ozs.	18 "	25	10	0	18
3.....	4 ozs.	2 "	12	24	10	38
4.....	29 ozs.	15 "	28	13	6	12

The requisites for the process are: (1) Cheap flaming fuel, *e. g.*, bituminous coal. (2) An iron ore, either as oxide or iron pyrites, the latter being especially desirable, if it contains silver. (3) A copper ore containing about 3 per cent copper for the formation of the copper matte to collect the silver.

The ores containing 25 per cent of zinc and over are crushed to pass a 4-mesh screen, and are then mixed by an archimedian screw with an equal bulk of fine coal. The mixture is then moistened and charged in lots of 600 lbs. into a furnace, of which the grate consists of perforated plates, the charge being spread on the grate in a layer about 4 in. deep. Air is forced through the charge from below at a pressure of about 2 ozs. per square inch, and a sufficient quantity of air is also forced through openings in the sides of the furnace above the layer of the ore to prevent the formation of sulphuric acid with the hydrocarbon vapor. The burning is completed in about 4½ hours, when the charge, which has not been touched during the operation, is in the form of a sintered mass, ready to go to the blast furnace containing the silver and other non-volatile metals and some zinc. The sulphur is driven off, and all of the lead and most of the zinc is volatilized, being collected in the form of a fume, out of which the pigment is made.

Iron pyrites, when necessary for a flux, are charged into a somewhat similar furnace and treated in a similar manner, except that only enough slack coal is used to start the pyrites burning, their sulphur contents being sufficient to supply the requisite fuel heat, while a higher blast (4 ozs. per square inch) is used, the burning being completed in from three-quarters to one hour.

Sinter from the zinc ore is mixed with the burned pyrite, copper ore, fluxes and fuel in the requisite proportions, and is smelted at a high temperature in a water-jacketed furnace of a greater proportional length than that of the ordinary blast furnace. Most of the zinc left in the charge passes off in the form of a fume which is saved, while the copper matte which collects the silver runs into an outside crucible with the slag and is tapped from time to time.

The ores containing about 22 per cent of zinc or less are smelted directly in a special furnace with the proper mixture of copper ore, fluxes and fuel. This furnace is water-jacketed and has two rows of tuyers on each side, the upper ones being about ten inches above the lower. The lower blast is supplied under a pressure of about two pounds to the square inch, and is preferably a hot blast. The upper blast is cold and run under a light pressure.

The ore and fuel are fed together continuously in a thin layer from 12 to 18 inches deep. For fuel, a mixture of coke and coal screenings is used, amounting to one-quarter of the weight of the ore. The blast from the lower tuyers plays upon the bath of molten matte, scorifying it and volatilizing all the lead and most of the zinc, which pass off through the thin layer of the unmelted portion of the charge in the form of a fume. The upper tuyers deliver a blast at the top of the charge, thus serving to keep up the necessary combustion and preventing the condensation of the volatile compound rising through it. The copper matte which collects the silver, as in the first method, runs into an exterior crucible with the slag, and is tapped from time to time.

The matte contains as much as 65 per cent copper and 250 ounces silver per ton. The slag contains six to ten per cent zinc and from three-fourths of an ounce to one and one-half ounces silver per ton of ore treated, no lead and only a trace of copper.

The fumes from all the furnaces, consisting of the zinc, lead and other volatile elements, are drawn from into chambers by means of exhaust fans and then forced through iron cooling conduits into long bags hanging from the roof of a building at some distance from the smelters. The gases pass through the bags where the solid contents of the fumes are caught, and from time to time shaken down into cars and taken to the refinery. This is subjected to a low, red heat in a closed tube containing a screw, which keeps the material in constant motion. By this means, all the deleterious volatile elements are removed, and the product is a marketable white pigment containing from 35 to 40 per cent of oxysulphate of lead and from 55 to 60 per cent of zinc oxide.

Some ores lose silver heavily, and others hardly any, ores containing copper or iron pyrites losing much less than others. As much as 95 per cent has been recovered, but generally the salvage is between 70 per cent and 85 per cent. Theoretically, the loss of silver should be confined to that in the pigment, and that in the slag, *i. e.*, in the former about 1 oz., and in the latter 1½ ozs. or 2½ ozs. per ton of ore treated; but there is a variable loss somewhere between, which has never been discovered. (Later returns show the silver loss to be under 2 ozs. per ton of ore treated, while there was a gain in the lead and gold over the assay of the raw ore).

The cost of treating the ore at Canon City is from \$5 to \$10 (average about \$6), including the production of the pigment and matte. The price of slack coal delivered at the works is 50 cents per ton, the coal mines being near the works. The price of coke is \$5 per ton at Canon City.

The cost of a plant to treat 250 tons of ore per day, producing about 20 tons of pigment and 40 tons of matte, is \$250,000.

The Best Methods of Arranging Load and Draft in Hauling on Farm Roads.

A late number of the *Deutsche Landwirtschaftliche Presse*, the leading agricultural journal of Germany, publishes the report of experiments made under the auspices of the Agricultural Institute of the University of Leipzig, for the purpose of testing practically the correctness of the extremely divergent views on the most advantageous mode of distributing the load and applying the draft in the case of farm wagons.

According to theory, on a hard and perfectly smooth plane it makes no difference on which part of the wagon the load rests or the draft is applied; and experiments made under these conditions confirm the prediction. But in farm practice we have to do, as a rule, with road surfaces more or less yielding; and the difference in the size of the front and hind wheels adds a complicating element, since the latter are supported on a larger section of their circumference than are the smaller wheels. In the latter, moreover, axle friction is greater than in the larger wheels.

The consequence is that, supposing the load to be so distributed as to rest equally on the front and hind wheels, the former sink more deeply into a soft road surface, causing an increased resistance as compared with the hind wheels. It seems reasonable that in order to equalize the resistance between the two sets of wheels, the front wheels should be eased by every available means, the more as, in case the hind wheels track with the front ones, the latter have to "break the way" for both.

The experimental tests were made by means of a specially perfected self-recording dynamometer, by which not only the average draft, but also its variations from one moment to another were accurately shown. These automatic diagrams are specially interesting in that they show in the most striking manner the extent to which the wear and tear on the team is aggravated by the constant succession of jerks, and how important it must be to obliterate these jerks by some equalizing appliances before they reach the draft animals. The averages given in the tables below

were, of course, obtained by a proper discussion of these diagrams in connection with previously determined constants of the dynamometer; the results are expressed in kilograms of weight required to overcome the resistance, by draft. The wagon was, of course, specially selected for good construction; its weight was 1051.5 kilograms (2313.3 pounds). A team of steady oxen were used for draft, and comparative trials were made in every case between hauling on a common field (dirt) road and a stubble field.

The first set of experiments was made with a load of 1440 kilograms (3168 pounds) and without varying the ordinary attachment of the traces. The load was alternately put entirely on the front wheels, and then on the hind wheels, with the results as a given below.

	Field Road.	Stubble.
Load on the front wheels.....	73.8	466.0
Load on hind wheels.....	60.3	381.6

Calling the draft when the front wheels were loaded, 100 per cent, we obtain the following figures:

	Field Road.	Stubble Field.
Load on front axle.....	100.0	100.0
Load on rear axle.....	81.7	81.9

Trial set No. 2 was made on the following day under the same conditions, with a two-horse team instead of the ox team; the results were practically identical, showing in each case an advantage of from 10 to 13 per cent in favor of loading the rear wheels.

A third set of experiments was now made, including one with the load evenly distributed between the front and rear trucks, but with an increased weight, amounting to 1680 kilograms (3696 pounds). The results were:

	Field Road.	Stubble Field.
Load on front truck.....	112.5 kg.	368.1 kg.
Load evenly distributed.....	108.9 kg.	298.8 kg.
Load on rear truck.....	92.7 kg.	328.5 kg.

Or in per cents:

Load on front truck.....	100.0 per cent.	100.0 per cent.
Load evenly distributed.....	96.8 "	81.2 "
Load on rear truck.....	82.4 "	89.2 "

The divergent result in the case of the stubble field experiment and evenly distributed weight is attributed to the accidental choice of a comparatively dry ridge instead of the well-soaked lower ground. However, taking all the trials together, there can be no doubt of the material advantage of loading the front truck as lightly as possible.

The next points experimented on were the influence of the point of attachment of the draft, or traces, and that of the greater or less length of the latter.

One set of experiments, made to compare the results as between an ordinary field road and a regular driveway, gave the following percentage results:

	Field Road.	Driveway.
Attachment low, traces long.....	100.0	100.0
Attachment low, traces short.....	77.0 per cent.	81.9 per cent.
Attachment high, traces long.....	71.8	80.9 "

These measurements confirm the current assumption that short traces lighten draft, as derived from experience. That the difference is less on the smoother driveway than on the dirt road in the field also agrees with the assumption, since on a perfectly smooth surface there would be no difference; the effect of short traces being to facilitate the lifting of the load over the inequalities of the roadway.

As between the field road and the stubble field, the following percentage results were obtained:

	Field Road.	Stubble Field.
Attachment low, traces long.....	100.0	100.0
Attachment low, traces short.....	89.6 per cent.	90.0 per cent.

Trials were also made to determine the effect of attaching the draft at the end of the wagon tongue. The following table summarizes the results obtained on the stubble field:

Attachment low, traces short.....	298 kg. or 89 per cent.
Attachment low, traces short.....	311.4 " or 100 "
Attachment at end of tongue.....	339.3 " or 109 "

Other experiments showed this difference to be still greater when, in attaching the draft at end of tongue, the load was placed on the front truck.

While it is not pretended that these experiments settle definitely the several points, they serve to point out the directions in which advantages in lightening draft may certainly be gained; namely, by disposing the load as near as possible to the rear truck, and by using short traces. The fact that draft animals hitched to the end of the wagon-pole (as in teams of more than two) do not work as advantageously as the wheel horses hitched with short traces, though well recognized by the practice of using the strongest animals in the latter position, is now, for the first time, demonstrated by measurement.

Collaterally, this series of trials serves well to illustrate the importance of good, smooth roads, in which all these differences are reduced to a minimum and the best results can be obtained under greatly varied conditions, as they must unavoidably be in practice. It may well, therefore, serve as a text to those of our citizens who, of late, have manifested such an active interest in road improvement. —Prof. E. W. Hilgard in Pacific Rural Press.

Scientific Progress.

Alloy in Metals.

Exact alloys of metals are often difficult to make, and with many a very small quantity of alloy greatly affects their qualities and produces some peculiar and unaccountable phenomena in working the metal, says the *Scientific American*.

The presence of 1-2000 of an ounce of antimony per pound of lead increases the activity with which it oxidizes and burns in the melted state. Lead containing more than 1-1000 of an ounce of copper per pound is unfit for the manufacture of white lead, on account of its coloring properties. Gold, with an alloy of 1-2000 of its weight of lead, is extremely brittle. Nickel was regarded as a metal which could be neither hammered, rolled nor welded, until it was discovered that the addition of 1-1000 part of magnesium or of 3-1000 of phosphorus makes it malleable and weldable to iron and steel. One-twentieth of an ounce of iron to one pound of copper renders the copper hard and brittle. Copper containing 1-1000 of its weight of antimony or bismuth cannot be used for making rolled brass. Zinc mixed with copper to the amount of 1-10 of an ounce per pound makes the copper red short. One-sixth of an ounce of arsenic makes copper hot short, while $\frac{1}{3}$ of an ounce makes it cold short. Some of the copper of commerce, made from ores containing other metals, sulphur, arsenic and silicon, is sometimes the cause of serious trouble with manufacturers in the rolling and stamping of copper and brass goods.

The electric conductivity of copper is largely modified by small admixtures of other metals, as with one-half of one per cent of iron its conductivity is reduced 60 per cent, as also with varying alloys of other metals of low conductivity.

The remarkable addition to the strength of metals by the fractional mixture of alloy of other metals or substances is a notable feature of modern metallurgy.

Copper, having a tensile strength of 25,000 pounds, by an addition of six per cent of tin may be equal to 28,000 pounds, but with the addition of one to two per cent of phosphide of tin and copper its tensile strength is increased to 80,000 pounds or more per square inch.

The addition of aluminum to copper in the small proportion of one per cent, largely increases its tenacity, and at 7½ per cent aluminum is equal to 60,000 pounds, and a ten per cent alloy 90,000 pounds per square inch, the highest being a test at the Washington Navy Yard of 114,000 pounds tensile strength.

The minute fractional alloys of aluminum and nickel with steel, as well, also, as its constituents, carbon, sulphur, phosphorus and silicon, are well known and need not be repeated.

Soap Suds for Calming Waves.

The remarkable action of oil upon waves is well known, says *Nature*. This phenomena led the officers of the steamship Scandia, of Hamburg, to make an experiment upon the same principle that was very successful and that appears to us worthy of mention. During its last trip to the United States the vessel, while in midocean, was attacked by a very heavy storm. It then occurred to the officers to dissolve a large quantity of soap in tubs of water. Having thus obtained several hundred gallons of soap suds in a very short time, they threw it overboard in front of the ship. The effect was almost instantaneous, and the vessel soon began to navigate without difficulty. Her officers at once addressed a long report to the Hydrographic Bureau of the United States, giving an account of their voyage, the storm, and the means that they employed to still the waves. They conclude by saying that, although soap suds

do not produce absolutely all the effects upon water that oil does, it at least suffices to break the force of waves in most cases. Besides, this method recommends itself to transportation companies careful of their interests. Soap suds is much cheaper than oil, and a relatively large quantity of soap can be carried without encroaching too much upon the space set apart for passengers and merchandise.

An Idea.

TO THE EDITOR:—When the explorers toward the North Pole reach the last line known, the question which they address to one another is, What path are we now to engage in? Is it leaning toward the east or west longitude? and so forth and so on. They are reflecting, and, as people groping in the dark, they make their attempts, which so far have not helped them to discover a road to attain their aims.

I have an idea which, it seems to me, could be communicated to them: Have a photographic balloon, small in size, and captive, so that when having reached the highest iceberg it could take a picture of the surroundings. Then the explorers would know what is above the icebergs, which close to them the farther horizon. They would know whether land is near or that an extensive sea separates them from it. Then a picture of the color of the water should be taken, which would reveal to them the condition of the outward climate. Even if the pictures were a little confused, the explorers could trace the green of the land, or the blue or yellow or green of the waters, or the white of the ice. They would know what is above or on the other side of the icebergs, and from that knowledge direct their course.

The material with which to fill the balloon could be obtained from a fire made of straw, if they did not wish to carry gas with them. That the picture could not be produced before the proper height is attained, the balloon should be covered with divided cloth put upon a frame, both halves to be kept closed by a string running along the captive rope, and, when desired, the explorers could pull that string and the silk of the balloon would become exposed to the rays of the sun; and the picture, when made, being submitted to chemical preparations, would be instantly produced; then bringing it down, the explorers could study it and act accordingly.

Now for their comfort. Before starting on they should establish several provision stores along the road they intend to follow until reaching the last spot known, said stores to contain dry edibles, wine, whisky, and olive oil. The last precaution is very necessary; it is a preventive against irritation of the throat and lungs, and it lubricates the digestive organs and all their conduits. They should also have some white vaseline, to apply on the eyelids during the night, and what would go into the eye would be a help. Then some fuel, one or two skin suits and blank books. With all these, the explorers would not apprehend starvation, nor death from cold.

The photographic apparatus should be placed upon the floor of the circle surrounding the rope of the balloon, and a string attached to each covering would unite them, passing through a little ring fixed to the rope and descending along it to be again united at man's height to a simple ring hanging there, and, by means of two small rings, the explorers could pull it up and let go when the photograph was taken. Then all would be over and the balloon brought down. Why should not the rope be of thin wire? There should be one apparatus at each point of the compass—a kodak would, perhaps, answer the purpose.

Mechanical Progress.

Battle Ships and Monitors.

"Taking first the battle ships," says W. A. Dohson in the *Popular Science Monthly*, "we find them to be, of all the types of war vessels, the most powerful in the feature of offense and defense; they are intended to stand and fight, to give and take blows, like gladiators in a prize ring; and the reason can be plainly seen when we appreciate the fact that an enemy can bring his battle ship within twelve miles of our large seacoast cities, and there taking up a position of vantage, secure from any attack by land, shell the city; the only vessel, then, that can dispute possession with him, point by point, is a ship of similar powers of doing battle, however successful an attack by torpedo boat, either surface or submarine, may be when conditions are suitable. The points, therefore, to be emphasized in the design are protection and armament, or the power to deliver heavy blows with the ability to withstand those of its antagonist.

As a purely harbor-defense vessel the Monitor stands pre-eminent, the entire hull and battery being protected by armor, and at the same time offering such a small target that it is extremely difficult to hit; but its military value is very seriously impaired when in a seaway, by the short distance of the guns above the water, it being impossible to use them in a heavy sea. Perhaps the vessels most useful in all-around work are the armored cruisers, as they are intended to have great speed, great endurance, good capable of coping with vessels inferior only to battle ships, with a very considerable amount of protection afforded to the hull and armament; their function in war is to capture the commerce destroyers of the enemy, to act as commerce destroyers themselves, and to convoy and protect fleets of large and fast merchant vessels. To accomplish these purposes great speed is necessary, either to overtake or convoy swift merchantmen; great endurance of coal supply, to enable them to keep the sea for long periods on the path usually frequented by merchant vessels; and offensive and defensive power sufficient to enable them to successfully resist the attacks of vessels of their own class.

How Granite Columns Are Turned.

According to the census reports, granite for columns, balusters, round posts and urns is now worked chiefly in lathes, which for the heaviest work are made long enough to handle blocks 25 feet long and five feet in diameter. Instead of being turned to the desired size by sharp cutting instruments as in ordinary machines for turning wood and metal, granite is turned and ground away by the wedgelike action of rather thick steel disks, rotated by the pressure of the stone as it slowly turns in the lathe. The disks, which are six or eight feet in diameter, are set at quite an angle to the stone, and move with automatic carriage along the lathe bed. Large lathes have four disks, two on each side, and a column may be reduced some two inches in diameter the whole length of the stone by one lateral movement of the carriage along the bed. The first lathe is for turning granite cut only cylindrical or conical columns, but an improved form is so made that templates or patterns may be inserted to guide the carriages, and columns having any desired swell may be as readily turned. For fine grinding and polishing the granite is transferred to another lathe, where the only machinery used is to produce a simple turning or revolution of the stone against iron blocks carrying the necessary grinding or polishing materials. Blocks are prepared for lathe work by being roughened out with a point, and by having holes chiseled in their square ends for the reception of the lathe dog and centers. This principle of cutting granite by means of disks re-

volvied by contact with the stone has been applied to the dressing of plane surfaces, the stone worked upon being mounted upon a traveling carriage and made to pass under a series of disks mounted on a stationary upright frame.—*Mechanical News*.

Pumping Coal to Market.

There was something strikingly novel to most people who visited the last World's Fair in the notion of pumping a fuel supply to the power plant of that great show, from a point many scores of miles away. The marvel consisted, perhaps, more largely of the successful use of crude oil on so large a scale in feeding fires under steam boilers than in the mode of shipment. It has, however, been proposed to pump coal to market in a similar way. The *Engineering News* recently discussed such a scheme at length. This, obviously, is a more remarkable idea, for coal is a solid. But the inventor, W. C. Andrews, meets this difficulty by crushing the stuff and mixing it with water. It has been suggested that not merely the vast heaps of culm which are now going to waste in the mining regions, but the whole output of the mines, might thus be sent to the consumer, the great recommendation of the plan being its economy. Coal could be "pumped to market," it is affirmed, for one-tenth the cost of rail transportation, if there be a steady demand. Still another gain would be secured in the operation of mining were this system generally adopted, for then it would be unnecessary to avoid producing a large proportion of "slack" or culm.

The coal could be reduced to dust, according to some estimates, for from three to five cents a ton, and washed free from pyrites, slate and other impurities for five cents more. This latter process would leave it in a greatly improved condition and increase its market value. It would then, according to the plan under consideration, be mingled with its own weight of water, and thus be forced through pipes as easily as is oil. Coal being lighter than most other minerals and but little heavier than water, it would remain in suspension easily. Absence of grit would prevent erosion of the pipes, and nothing of value could be withdrawn from the coal by soaking. Moist coal, when exposed to the air, deteriorates rapidly and is liable to spontaneous combustion; but so long as the fuel is kept under water in settling basins, these drawbacks would not be experienced. And where the coal is not to be used immediately, it would be stored in this manner; then it would be stirred up again before pumping to consumers.

At best two things are requisite for the ultimate success of this scheme: A good way of disposing of the water eventually, and a satisfactory mechanism for burning coal dust. That this latter object will soon be attained, if it has not been already, there is much reason to believe, as a writer in the *New York Tribune* recently indicated. As for the fluid which is employed in transportation, Mr. Andrews would get rid of most of it by means of settling basins. Even with only 10 or 20 per cent of water, it has been estimated, the coal could still be forced through pipes for short distances, and various driers could then be devised to complete the work, if completion were desirable. But the *Engineering News* calls attention to a fact which possibly the original proposer of this idea had not thought of: If it were feasible to feed wet coal dust into a furnace, the cost of vaporizing the moisture therein would be small. A mixture of half and half, says the *Engineering News*, would involve a loss of only 8.5 per cent of the heat from good coal, and 11 from poor coal, whereas by the settling basins the proportion of water could be reduced from 50 to 10 or 15 per cent, and the heat loss reduced to 2 or 3 per cent. As yet it does not appear that any wholesale test has been made of this plan.

EVERETTE'S MINING OFFICE.

(Pioneer Mining Geologist's Office of the Pacific Northwest.)

Mining Law, Mine Examinations, Metallurgy.

ASSAYING AND ANALYSIS.

"Consulting Associate Mining Attorney at Law."

Will examine and report upon "Title and Exact Value" of GOLD, SILVER, IRON, COPPER, COAL, IRON, CLAY or other MINERAL PROPERTIES in any part of the world. Any information mining men may desire to know, relative to the mineral or coal resources of the entire Pacific Northwest, will be honestly given.

DR. WILLIS E. EVERETTE, 1818 E. ST., Tacoma, State of Washington, U. S. A.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$3.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

The Twenty-Seventh Edition of a Deservedly Popular Technical Book, The Painter, Gilder and Varnisher's Companion, Revised, Enlarged and Improved.

JUST READY.

Price, \$1.50.

Free of Postage to any Address in the World.

THE PAINTER, GILDER AND VARNISHER'S COMPANION.

Comprising the Manufacture and Test of Pigments, the Arts of Painting, Graining, Marbling, Staining, Sign-Writing, Varnishing, Glass-Staining, and Gilding on Glass; together with Coach Painting and Varnishing, and the Principles of the Harmony and Contrast of Colors. Twenty-seventh edition. Revised, Enlarged and in great part rewritten. By William T. Brant, Editor of "The Varnisher, Lacquer, Plating, and Sealing Works." Illustrated. In one volume, 12mo, 415 pages, bound in cloth.

Price \$1.50, free of postage to any address in the world.

A circular of 20 pages, showing the full Table of Contents of this Useful and Popular Book, will be sent free of postage to any one in any part of the world who will furnish his address.

HEALD'S

BUSINESS COLLEGE.
24 POST STREET.....SAN FRANCISCO.
FOR SEVENTY-FIVE DOLLARS

This College instructs in Short-hand, Type-Writing, Book-keeping, Telegraphy, Penmanship, Drawing all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils. Our school has its graduates in every part of the State. SEND FOR CIRCULAR. E. P. HEALD, Pres. O. S. HALEY, Sec.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, Jr.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdies, rockers, undercurrents, etc.; also describes method of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

TUBBS CORDAGE CO.
(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tanned Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

611 & 613 Front St., San Francisco, Cal.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 80 cents additional per volume.

Electricity.

The Cause of Trees Being Struck by Lightning.

The frequent striking of trees by lightning is a traditional phenomenon that is well known, but the causes of it are not so precisely known, although it is, in a manner, a primordial electric manifestation. Mr. D. Jonesco has recently made a series of interesting experiments on this subject, the results of which have been communicated by him to the Agricultural Society of Brabant, says *La Genie Civil*.

Mr. Jonesco has ascertained that certain trees attract lightning better than others. Starting from this, he has endeavored to find out how the various forest trees behave with respect to electric discharges, and has ascertained that the greater or less conductivity of trees should be taken so much the less into consideration in proportion as the electric tension is stronger. When the latter is sufficiently elevated, any tree may be struck by lightning; but differences exist from the moment that the tension is feeble. The richness of the wood in water, contrary to what is generally believed, has no influence upon the conductivity of the living wood for the electric spark. On the contrary, such conductivity depends much upon the richness of the wood in starch and oil. Mr. Jonesco, in accordance with Mr. A. Fischer on this subject, consequently distinguishes trees as oil trees and starch trees, and reaches the following conclusions:

The green wood of trees is in all cases a bad conductor of electricity, and so much the worse in proportion as the tree is richer in oil. On the contrary, the green wood of amyloseous trees, poor in oil, conducts electricity relatively well. Living wood is a much better conductor than dead. This existence of dead branches in trees of both categories, therefore, increases the danger of lightning. This is an observation of no small importance from the standpoint of the safety of houses situated in the vicinity of large trees. The cambium and bark are better conductors than the wood, but these parts are relatively to the bulk of the tree, too slightly developed to modify its electric conductivity. The latter, therefore, depends upon the wood only, since, according to Mr. Jonesco, the foliage is equally without influence upon the relative conductive power of trees for the electric spark.

The results of these researches are confirmed in the statistics given by Mr. Jonesco, and which consist in the observations made upon lightning strokes and trees since 1847 by the superintendency of forests of the principality of Lippe. It has been found, for example, that the oak is much oftener struck than the beech. Now, the first is a type of starch tree and the second a type of oil tree. On another hand, the observations made establish the fact that the frequency of lightning strokes is greater in the dry than in the other branches. Besides, the same statistics go to prove that the danger of lightning has no relation with the character of the soil. Although the highest figures are shown in hard and sandy ground, this is due to the fact that starch trees grow in such soil, but the nature of the latter is without influence.

The Purification of Lead by Electrolysis.

An ingenious application of electrolysis is being made in the purification of lead, and the recovery of silver from argentiferous lead which results in the production of chlorine, says London *Electricity*. The chlorides of calcium and magnesium are decomposed with lead nitrate, and the lead chloride so formed is utilized for the electrolytic production of chlorine, whilst the nitrates of calcium and magnesium, which are also the results of the decomposition,

are heated for the recovery of the nitric acid, which is used for dissolving fresh quantities of crude oxidized lead to form lead nitrate. Silver and other metals may be precipitated from this solution by the addition of spongy lead. As an alternative way of working, hydrochloric acid is used instead of the chlorides for decomposing lead nitrate (or acetate), the products being lead chloride and free nitric acid, which may be used as before for dissolving fresh quantities of previously oxidized lead. The fused chloride is electrolyzed in a glazed earthenware or enameled iron vessel, kept at a suitable temperature. The cell is closed on the top, and is provided with a feed pipe for the lead chloride, a chlorine outlet pipe, and a siphon for drawing off the purified molten lead. The carbon electrodes, alternately, anodes and cathodes are securely fastened on the lid. In another arrangement the carbon plates are all anodes, the molten lead forming the cathode. The conductivity of the carbon electrodes may be improved by making them with a core of iron or other metal in the form of a plain corrugated or perforated surface.

Relation of Heat to Electricity.

The effect of low temperature upon the physical properties of matter is very striking, says Prof. A. E. Dolbear in the *Cosmopolitan*. For instance, it is found that the vigor of chemical action decreases and the elements apparently lose their ability to combine as their temperature is lowered. Thus phosphorus and oxygen, which so energetically combine at ordinary temperatures, become more and more chemically inert as this temperature is decreased, until at 200° below the freezing point of water they appear to be unable to unite. This may be otherwise stated by saying that in the absence of heat there is no chemical affinity. Now, heat is known to consist in the internal vibratory motion of atoms and molecules of matter, so that it appears that in the absence of such vibratory motions there is no possibility of chemical action. On the other hand, as the temperature falls, the magnetic and electrical qualities of some, or all of the elements, are exalted in a proportional way. Thus, oxygen, which is feebly magnetic at ordinary temperature, becomes strongly magnetic at 200°; and when liquefied, as it easily may be at such low temperature, it behaves like iron to a magnet, and will adhere strongly to its poles.

At ordinary temperatures, copper is six times better a conductor of electricity than iron, but the conductivity of each is increased by cold. Copper is tentimes better as a conductor of electricity at 100° than it is at the freezing point of water, and the conductivity of iron increases at a still greater rate until iron becomes as good as copper. It has been proposed to inclose electric conductors in pipes to be kept very cold by some of the well-known processes for extracting heat, such as are in common use for ice production, as the amount of copper needed would be less as the temperature was less. It may be some time before this plan is carried out; but that it is possible to thus reduce the cost of electrical conductivity by running an engine to produce cold is certain, and it will be done when the cost of copper becomes commercially comparable with the cost of running an engine for such a purpose.

Experiment seems to indicate that all the metals are thus affected by cold, and that at absolute zero their electrical conductivity becomes infinite, or, as it is more generally stated, the electrical resistance of metals becomes zero. The other properties of substances are also profoundly changed so as to be radically different from what they are under ordinary conditions. Cohesion, tensile strength, malleability, etc., become less and less, so it seems altogether probable that the qualities and states of matter so

familiar to us as solids, liquids and gases depend absolutely upon temperature, and that at absolute zero there would be neither solid nor liquid nor gas, and that electrical and magnetic qualities would be at a maximum. This opens up a great field for speculation as to the nature of matter itself, when most of what we call its properties may be emptied out of it by simply reducing its vibratory motion.

Useful Information.

History of Matches.

The lucifer match has attained its present high state of perfection by a long series of inventions of various degrees of merit, the most important of which resulted from the progress of chemical science. Starting from the ingenious tinder box of our Saxon ancestors, the first attempt, so far as known, to improve on the old sulphur match was made in 1805 by Chancel, a French chemist, who tipped cedar splints with a paste of chlorate of potash and sugar. On dipping one of these matches into a little bottle containing asbestos wetted with sulphuric acid, and withdrawing it, it burst into a flame. This contrivance was introduced into England some time after the battle of Waterloo, and was sold at a high price under the name of Prometheans. Some time after this a man opened a shop on the Strand. It was named the Lighthouse. An ornamental open moiré metallique box, containing 50 matches and the sulphuric acid asbestos bottle, was sold for a shilling. It had a large sale and was known in the kitchen as the Hngh Perry.

Heurtner also brought out Vesuvians, consisting of a cartridge containing chlorate of potash and sugar and a glass bead full of sulphuric acid. On pressing the end with a pair of nippers the bead was crushed and the paste burst into flame. This contrivance was afterward more fully and usefully employed for firing the gunpowder in the railway fog signals.

We now come to Walker. He was a druggist at Stockton-on-Tees, and in 1827 produced what he called Congreves, never making use of the word lucifer, which was not yet applied to matches. His splints were first tipped with the chlorate of potash paste, in which gum was substituted for sugar, and there was added a small quantity of sulphide of antimony. The match was ignited by being drawn through a fold of sandpaper with pressure; but it often happened that the tip part was torn off without igniting; or, if ignited, it sometimes scattered balls of fire about. These matches were held to be so dangerous that they were prohibited by law in France and Germany.

The first grand improvement took place in 1833 by the introduction of phosphorus into the paste, and this seems to have suggested the word lucifer, which the match has ever since retained.

When phosphorus was first introduced to the match-maker its price was \$20 per pound, but the demand for it soon became so apparent that it had to be manufactured by the ton, and the price quickly fell to 60 cents per pound.—Exchange.

History of Iron Making.

Iron was used before history was written. The stone records of Egypt and the brick books of Nineveh mention it. Genesis (ix, 22) refers to Tubal Cain as "an instructor of every artificer in brass and iron," and in Deuteronomy (iii, 11) the bedstead of the giant Og was "a bedstead of iron." The galleys of Tyre and Sidon traded in this metal; Chinese records ascribed to 2000 B. C. refer to it; Homer speaks of it as superior to bronze. The bronze age came before the iron age, because copper, found as a nearly pure metal, easily fuses, and with another soft metal—tin or zinc—alloys into hard bronze; while iron, found only as an

ore, must have the impurities burnt and hammered out by great heat and force before it can be made into a tool. The word sometimes translated "steel" in our English Bible really means bronze or brass; but steel was distinctively known to the later ancients. Pliny the elder wrote in the first century of our era: "Howbeit as many kinds of iron as there be none shall match in goodness the steel that comes from the Seres (Chinese), for this commodity also, as hard ware as it is, they send and sell with their soft silks and fine furs. In a second degree of goodness is the Parthian iron."

Asia probably made more iron and steel 30 centuries ago than it does to-day. About the time of the first Olympiad, 776 B. C., there is authentic record of the use of iron in Greece, and Lycurgus used it for the money of Sparta. Iron and steel weapons of war began to displace those of bronze before the battle of Marathon. The Romans learned iron-making from the Greeks and the Etruscans—their mysterious and highly civilized neighbors—and obtained iron largely from Corsica, where the mines had been worked from the prehistoric period. The Roman legionaries found in Spain steel weapons of the finest temper, and Diodorus says that the weapons of the Celtiberians were so keen "that there is no helmet or shield which cannot be cut through by them." Toletum (now Toledo) was then as famous for its sword blades as afterward in the Middle Ages. Cæsar found the painted Britons fighting with spear-heads of bronze, but wearing armlets of iron, and remains of pre-Roman forges are still found in England and Wales. The Germans knew the art of sword-forging, and their legends of dwarfs and trolls with magic swords point to an earlier people, adepts in mining and metalurgy.—From "A Bar of Iron," edited by R. R. Bowker in Harper's Magazine for February.

Electric Canal Propulsion.

Electric propulsion on canals is not altogether so new a thing as those who read of the Erie Canal enterprise may have been lead to think says *Cassier's Magazine*. For some time past, in fact, electric power has been applied to identically the same purpose in France, on the Canal du Bourgogne, and illustrations which have appeared in several French papers of the electrically equipped boats there used, have shown the arrangement adopted to be similar in many respects to that only recently carried out in the United States. On the French boats, however, the electric motors are not coupled to the propeller shafts, but, instead, drive trains of gearing by which a chain on the bottom of the canal is clutched, thus pulling the boat along. Chain haulage of this general kind has long been in use on some of the European waterways, and, in itself, is nothing new, simply illustrating in this instance another example of electric development of an old method of propulsion. The double trolley system is employed, and the current is furnished by generators driven by turbines, the canal company controlling near-by water power which could be readily utilized.

Specific Gravity of Gas.

Herr Max Arndt, of Aix, has patented in Germany a curious method of finding the specific gravity of a gas. He counterpoises on a balance an inverted bell with a very narrow mouth, and into this he lets the gas whose specific gravity is to be ascertained. If the gas is lighter than air, the bell rises; if heavier, it sinks. The apparatus is so constructed as to draw air from the bell, as well as to let air into it.

If one wishes to cool a hot dish in a hurry, it will be found that if the dish be placed in a vessel full of cold salt water it will cool more rapidly than if stood in water free from salt.

Metallurgy and Ores.

SELBY
SMELTING AND LEAD CO.
416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

—AND—
ASSAY OFFICE.

Highest Prices Paid for Gold, Silver
and Lead Ores and Sulphurets.

—MANUFACTURERS OF—

**BLUESTONE, LEAD PIPE, SHEET LEAD,
SHOT, ETC., ETC.**

—ALSO MANUFACTURERS OF—

Standard Shot - Gun Cartridges,
Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

**ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,**

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND
CHEMICAL APPARATUS.

61 & 65 First St., cor. Mission, San Francisco

We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scor-
fers, etc., including, also, a full stock of
Chemicals.
Having been engaged in furnishing the sup-
plies since the first discovery of mines in the
Pacific Coast, we feel confident from our experi-
ence we can well suit the demand for these
goods, both as to quality and price.
Agents of the Denver Fire Clay Co. and
for the Morgan Crucible Co., Battersea,
England. Also for E. G. Denniston's Silver
Plated Amalgam Plates. The plates of this well-known
manufacturer are thoroughly reliable, and full weight
of Silver guaranteed. Orders taken at his lowest prices.
Our Illustrated Catalogue and Assay Tables sent free
on application.

JOHN TAYLOR & CO.

**Dewey & Co.'s Scientific Press
Patent Agency.**

OUR U. S. AND FOREIGN PATENT AGENCY
presents many and important advantages as a
Home Agency over all others, by reason of long
establishment, great experience, thorough sys-
tem, intimate acquaintance with the subjects of
inventions in our own community, and our
most extensive law and reference library, con-
taining official American and foreign reports,
files of scientific and mechanical publications,
etc. All worthy inventions patented through
our Agency will have the benefit of an illustra-
tion or a description in the MINING AND SCIENTIFIC
PRESS. We transact every branch of
Patent business, and obtain Patents in all coun-
tries which grant protection to inventors. The
large majority of U. S. and Foreign Patents
issued to inventors on the Pacific Coast have
been obtained through our Agency. We can
give the best and most reliable advice as to the
patentability of new inventions. Our prices
are as low as any first-class agencies in the
Eastern States, while our advantages for Pacific
Coast inventors are far superior. Advice and
Circulars free.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute
angle inclining toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vexation and loss caused by the
frequent breaking of the flanges of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight ribbed surface for
the space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight ribs
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes thereof from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testin
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt.
It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assay; Examples of Dressing; The Melting in
Crucibles; Scorchification; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ore Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Ore; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1888. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and
separate from Part I, and treats of Gold and Silver Bullion:
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhard's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and
Cobalt; Ochromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.

One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers, No. 220 Market St., San Francisco.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED
Sept. 19, 1893. }

CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.

{ FRANK BARRERE,
Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE PACIFIC BRANCH UNION IRON WORKS, 127 FIRST STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

—SAVED—

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE (at present).....\$350 EACH,
Including Prepared Canvas Belt.

FALLS MINE, I.O., SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ore. It is doing OLEANER and CLOSER work than I had believed possible for any concentrator to accomplish. Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

NOTICE TO GOLD MINERS! SILVER-PLATED AMALGAMATED PLATES For SAVING GOLD!

IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Calaveras.

Very Rich Rock.—San Francisco Post: Henry G. Hanks, the well-known assayer of this city, has just completed the assay of some fabulously rich rock from the Carson Creek mines of Calaveras county. The ore which was taken from the incline now being run at a depth of about 400 feet from the surface goes \$33,000 to the ton, and all that the lucky owners are now interested in is the extent of the new find.

In speaking of this matter Mr. Hanks, who has the reputation of being one of the most careful and conservative men in the business, said that assays of the kind were apt to be misleading among people who do not understand mining. While this could be accepted as an indication of highly mineralized vein matter in places, it should not be supposed that the average of the ore extracted would run anything like this amount quoted. Enormously rich specimen rock has been taken out of this mine at times in the upper workings by former owners, and in adjoining properties, notably the Carson Hill and Morgan mines, "bunches" or "pockets" have at times been discovered, from which thousands of dollars were taken with a hand mortar.

The same can be said of a number of mines in Tuolumne county, which are now worked almost entirely for "pockets." In others, again, the ore contains a large amount of tellurium, and samples of the kind are now on exhibition at the Midwinter Fair which will run as high as \$26,000 to the ton. Many of these properties were abandoned years ago, owing to the lack of knowledge in regard to saving the gold in this particular class of ores, and were finally disposed of for a song to the present owners. Now, with the improved system in milling and reduction plants the former difficulties are overcome and very little of the metal in the ore escapes by volatilization or otherwise.

The Carson Creek property was formerly known as the Jones mine. It was worked with good results to a depth of about 240 feet on an incline. After laying idle for some years it was purchased by some Eastern capitalists, who have since expended considerable money in the work of development. They have carried the incline down from the old workings a distance of 460 feet, where the discovery has just been made which has attracted so much attention to the property. As soon as a station has been cut out drifting will begin to determine the extent of the new find.

The Carson Creek location only covers a claim of 20x800 feet, but the company also owns an extension covering 600x1000 feet, the ordinary sized claim under the State mining laws.

The improvements consist of a new 40-stamp mill, with all the latest improvements. The formation is granite and slate. The mine, which is located four miles by wagon road from Angels Camp, is well situated, being in the neighborhood of the Utica, which turned out over \$250,000 in bullion last month, and other mines of historic interest as gold producers.

Mono.

TAUVERTINA MARBLE.—The great travertine discovery within sight of the Bridgeport Chronicle-Union office is attracting much attention and becoming widely known, and the exhibit of this fine building material, of which ancient and modern Rome had and has splendid buildings built of it, and which is said to be the most lasting building material known, has, at the Midwinter Fair, opened the eyes of the marble men and builders of the country. The Carson News says that Mr. Lindsey, the owner of the quarry, has orders for five carloads.

In this great find Mr. Lindsey has something better than a gold or silver mine, as it is not liable to "peter out," the work of nature continually adding to the deposit which now seems inexhaustible. This deposit of travertine is the only known one on this continent, and perhaps in the world, outside of Italy, where the builders of Rome obtained this lasting and beautiful stone.

Nevada.

WILL PUT UP A MILL.—Nevada City Transcript: Sam Peck and Wells Ashman have been testing the cemented gravel found near Mrs. Storey's residence, off from Orchard street, and have concluded to put up a mill to crush and work it. Several tons were hauled to Locklin's mill a short time since and crushed as an experiment. It paid at the rate of \$1 per ton. Owing to the immense quantity of the cement at hand, the ease and cheapness with which it can be handled, and the large amount that can be run through a mill in a given time, it is claimed that it can be worked at a good profit. There are thousands of tons of this cemented material lying exposed in the old hydraulic diggings, near where the mill will be erected. The success of this venture will no doubt cause other mills to be put up in many of the old gravel mines where the cement abounds.

HEAVY SNOWFALL.—Ormonde Cor. Tidings: The snow in this region at the present time is nearly everywhere. It is over head, it is under foot, and is in and out every crack and cranny of our dwelling houses. The snowfall immediately on the south Yuba river, at this place, has been comparatively light, but only a few hundred feet higher up on the hillsides and mountains it is any depth that a tenderfoot would be pleased to see it. At the California mine, five miles north from this place, the

snow is 13 feet in depth. At the Gambrinus mine, only a mile or so farther north, it is 16 feet deep; at Enreka it is 12 feet; at Enreka and Beauman summit it is 20 feet; at Faucherie lake 17 feet, and at Grouse ridge, at the head of Fall creek, eight miles northeast of this place, is over 20 feet in depth; farther both north and east the snow is much deeper. At the Eagle Bird mine the company are now employing somewhere between 20 and 80 men in prospecting the mine. The main shaft is now down about 750 feet, and tunnels are being run in different parts of the mine; should a new pay shoot of ore at any time be discovered, more men will be put on and mill started up again as usual. The Yuba mine is now clear of water and sinking the shaft is now in progress; it is to be sunk 200 feet deeper and the work is to be done by Chinamen.

At the Blue Jay mine, owned by Bangh & Bonney, four men are steadily employed in breaking and hoisting rock by windlass from their mine. Their ledge is from a few inches up to eight feet in width and a good deal of the rock is quite rich in free gold and galena sulphurets. As far as developed this mine is the richest one yet discovered in the Washington mining district, which is saying considerable, but it is a fact nevertheless.

The German mine at this place still remains closed down, and is more than likely to remain in the same condition for some time to come, or at least until the snow disappears so that teams can get in to the mine.

A TWENTY-STAMP MILL.—Telegraph: The Osborne Hill Mining Company will build a 20-stamp mill, with all the modern appliances, and it will be built as soon as there is a possibility of getting machinery and lumber on the ground. Supt. Goldstone informed us to-day that a contract for the necessary lumber for the mill would be let in a very short time. The site for the mill is just about as good as it could be, and the mine is looking fine and is in good shape for working.

Placer.

AN OLD MINE REOPENED.—Sacramento Record-Union: A company formed here last fall purchased an old and abandoned quartz mine at Horseshoe Bar, Placer county, which was worked years ago by the then Golden Rule Mining Company, and formerly owned by the late Horace Adame, C. H. Krebs and others.

The new Golden Rule mining directors are all old and well known Sacramentoans—William Gutenberg, Nelson Wilcox, Lincoln White, J. B. Patterson, E. J. O. Rother and James I. Felter, the secretary. The latter has been advised that the main vein was struck this week, and Superintendent Rother, who is a man of large mining experience, pronounces it a finely developed mother lode, rich in free gold and sulphurets.

Thirty years ago there were thousands of miners on the American river at Horseshoe and Rattlesnake bars and in the immediate vicinity, and millions of dollars were taken out of the bed of the river and ravines by the crude methods of mining then in use.

The present company purchased this property from L. L. Crocker and J. W. Smyth. The latter has resided there continuously for forty years, as a miner, merchant, farmer and fruit-raiser, and claims to be the pioneer producer of citrus fruits in Placer county and central California.

DRAFT OF TWENTY MEN.—Colfax Sentinel: The Paragon mine at Bath made a draft of twenty men last Saturday. It is expected that the men will soon be put on again.

Work is steadily being pushed on the tunnel in the Alta mine.

The Gold King mine at Green Valley is working a force of thirty men. The mill works first rate and the cement looks promising.

The new company recently organized to work the Willis Gould mine at Iowa Hill are very much encouraged by the prospects they have already found and think the mine will soon be one of the best on the divide.

It is rumored that the Dardanelle mine at Forest Hill is soon to be sold to a large company.

The work in the tunnel at the Golden Eagle mine at Shady Run, after a short stop owing to lack of timbers, will soon begin again.

The Pioneer mine is looking better now than ever before in its history. The ledge is a solid one, being highly mineralized and yielding from \$10 to \$25 per ton. The pay-chute is extensive, and has the promise of yielding a vast amount of money to its already wealthy owners. This mine has been paying regular monthly dividends for the past three years, and each month finds the prospects growing brighter. Fifty men are employed and the 20-stamp mill is kept going night and day.

Plumas.

FROM RICH GULCH.—National-Bulletin, March 15: Chas. Schneider came up from Rich Gulch a few days ago, where he is doing some prospect work. He reports the Hallated Bros. crosscutting the vein in the lower or "Blacksmith" tunnel of their mine. The face of the drift is in 239 feet. The tunnel was cut beside the immense ledge, the crosscutting of which shows it to be 30 feet wide. This body of ore is reported to prospect well.

ELIZABETHTOWN CHANNEL.—National-Bulletin: Work at the shaft on the Kellogg ranch is now progressing favorably, although there has been considerable trouble with the pumps. The shaft is now about 45 feet. The large pump will soon be put in, when it is expected sinking will proceed with less interruption.

RESUMED WORK.—Granite Basin Cor. National-Bulletin: Weber & Chate have again resumed work in their mine, which promises to be one of the richest in Granite Basin. They have a tunnel in 250 feet, and 60 feet of perpendicular slope. They expect to reach the ledge in a few days, being already in the formation of the ledge. There is a 50-foot shaft sunk on

it, from which the boys have already realized considerable. The last quartz that was taken from the bottom of the shaft was very rich, far exceeding in richness and in width any that was ever taken out before. There is a ten-stamp mill and also an arrastra on the property.

Angust Banner and father have a quartz ledge they discovered while prospecting last spring, which, although very narrow, carries large quantities of the precious metal, simply repaying in quality what it lacks in width. It is situated a mile from any mill, and there is no road near it as yet, but the owners did not propose to let such little things as that dismay them; so they procured a pack mule and packed out five tons of quartz, which they had crushed for a sample test. The results far exceeded their utmost expectations. They have been working on the ledge all winter, and the rock continues as rich as ever.

Siskiyou.

READY TO HYDRAULIC.—Yreka Journal, March 7: Frank Hall, the well-known mining operator, having lately purchased the Finley Tribe mine at Salmon River, has just completed a new ditch to the same, with intention of starting the giants this week, so as to have a long season in pipping the rich ground. He has also 30 men at work building a five-mile ditch to the old Harris claim, so as to start giants at work on that claim in a very short time. He says Salmon river has a large number of people in search of mining property, all the hotels being crowded, the new wagon road having proven a great incentive in the way of development. Over \$20,000 of capital has been invested in mines since last spring in Liberty mining district, Mr. Hall having expended \$6500 for the company he represents.

The miners along Klamath river, in the Honoluh district, are making preparations to commence wing-damming and putting in water-wheels as soon as the winter storms cease and the river falls to its normal condition.

The Spengler Bros., at mouth of Humburg creek, near Klamath river, have a large force of men at work, getting down on bedrock, aided by a stout little steam engine for hoisting out boulders and pay gravel.

Dietrich, the Oak Bar expressman, intends working his cinnamon mine, at head of Smith river, in Oregon, near the Siskiyou and Del Norte dividing line, during the coming summer. Besides finding cinnamon in good paying quantity, he also found platinum, which is claimed to be more valuable than gold.

On the Salmon mountain, between Etna and Sawyer's Bar, the snow is very deep, about 12 feet on level at the summit, and in some of the canyons considerable more by drifting. The mail and express is taken over for eight miles of the distance on snowshoes, the men employed easily packing a mail sack and packages to the extent of 75 or 80 pounds each. With the aid of horses and cattle the wagon road might be broken to permit the navigation of wagons or sleighs, but as the Salmon river people are well supplied with staples, the trouble and cost will hardly justify, as the special needed can be packed over without much difficulty on snowshoes. In a short time, unless we have more heavy storms, not likely at this late period, horses and mules can make the trip, or else the people will then take steps to break the road. The new wagon road has been a great benefit to the Salmon river section, and has caused many mining speculators to visit that section and purchase mining property, with the result of making it one of the most prosperous mining districts on the coast. In a few years more the business will become so extensive that the wagon road will be kept open all winter, as a necessity for the accommodation of travel and transportation of freight, express and mail matter.

GOLD IN A POCKET.—Yreka Journal, March 21: A man and his wife, mining on Yreka Flats, found \$200 in gold under some bowlders last week, a rich spot not disturbed during the flush times of the '50 period, when the flats yielded rich returns without much labor or cost, as the diggings were shallow. An old man who worked on the flats in early days has also been doing very well in scratching over old-worked ground, having lately returned from Idaho dead broke to make a living at the old places where he took out great quantities of gold in early days.

A party of young men who have leased the Scheld & Pellet claim on Greenhorn gulch are taking out good pay, giving one-fourth to the claim-owners for privilege of working same and using apparatus connected therewith.

There is considerable mining in all the old diggings this winter and spring, with the benefit of plenty of water, the best season in this respect ever known in Siskiyou, by reason of the storms coming in such regular rotation at stated periods to be of good practical use.

The miners at Hawkinsville, about two miles north of Yreka, and in all the gulches leading down to that place, are doing exceedingly well this season, with plenty of free water to keep their sluices supplied in washing the rich auriferous gravel found along the hedrock in all sections of Hawkinsville mining district.

In most of the high mountain gulches and creeks, such as Greenhorn, Humburg, Deadwood and Cherry creeks, in this vicinity, the snow is from two to three feet deep, but the warm rains of the past few days have been dissolving it rapidly, so that miners will soon be able to commence operations with good success until later in the season than usual. Along the foothills, where there is no snow, the miners are busily at work, as the melting snow higher up affords plenty of water for washing. At Indian, McAdams, Shackelford, Kidder, and several other creeks along west side of Scott valley, there is also an abundance of water, with a great amount of snow on the mountains above to keep up the water supply in benefiting the miners for placer, hydraulic and quartz mining.

The same may be said of the Salmon River, Cottonwood, Scott River, South Fork and other mining districts, to make the output of gold from Siskiyou for 1894 the greatest ever known in the history of the county.

Trinity.

TELEPHONE LINE.—Weaverville Journal: The La Grange Hydraulic Gold Mining Company has contracted with S. L. Blake and E. P. King for a telephone line to run from the end of its ditch near Rush creek to the boarding-house at the mine and thence into town. Work has already been begun on the contract; the material has been ordered, and the line will be pushed to completion as rapidly as the weather will permit. This line will be a great convenience to the company.

Tuolumne.

NEW MILL STARTS.—Independent: The Bnzard Roost is situated on the Stanislaus river near Parrott's Ferry, about 200 feet above the level of the river. The new five-stamp mill has been completed and the work of crushing has commenced. The owners do not know as yet the value of the ore, but say that it will reach a fair average. The shaft is now 100 feet in depth, with a crosscut of 85 feet to the vein and has run 57 feet on the course of the vein. This company has a free water power, taking the waste water from Vine springs.

The Seminole, near Summerville, is getting under headway as rapidly as the weather will permit. A new road is in course of construction to the property, and a foundation for their mill is nearly finished. Development work is constantly in progress, while some very rich rock is being taken out. This mine, it is said by competent judges, will be one of the best paying properties in the county in a short time.

Col. Coles, who has charge of a group of mines near Summerville, reports his properties looking well and that active operations will commence shortly.

Good prospects continue in the Cardinelle mine. Quartz shown in Sonora this week was thoroughly impregnated with gold.

The property of the Saratoga Development and Improvement Company, near Springfield, has been sold to Oakland parties.

It is reported that the Badger mine will start operations within a few weeks, by a San Jose company.

J. T. Bluet has leased the Sweeney mine, on the mother lode, in the interest of Wm. Johns.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—Following is a summary of the official news in letters from Comstock mines:

In the Consolidated California & Virginia mine on the 1650 level the drift running north from the east crosscut No. 1 from the north drift from the winze—down 52 feet—has been extended during the week 25 feet; total length 37 feet; continuing in porphyry, clay and quartz of low assay value. Have extracted from the workings in the vicinity of the winze—down 20 feet—25 tons of ore assaying \$35.85 per ton. The average assay value, per battery samples, of all ore worked at the Morgan mill during the week (43 tons and 1390 pounds) was \$34.33 per ton. Have shipped to the company's office in San Francisco four bars of bullion, assay value \$17,250, yield of 683 tons and 1390 pounds of ore worked at the Morgan mill. 1000 level—the Rule drift—the upraise from this drift started at a point 253 feet south of the shaft station has been carried up during the week 40 feet, continuing in porphyry, clay and quartz of low assay value. The east crosscut, No. 2, started from the drift at a point 527 feet from the shaft station, has been extended 20 feet; total length 69 feet; face in porphyry with clay and lines of quartz. The progress in these localities has been retarded during the week on account of repairs being made to the shaft between the 1000 and 1100 level stations by the West Consolidated Virginia & California Company, which required for that purpose the use of the shaft for a large portion of the time.

In the Ophir mine the recently started west crosscut on the 1465 level is up 33 feet. The face continues in porphyry, clay and quartz. An advance of 52 feet was made during the week in reopening and repairing the Central tunnel, making the total length of the drift reopened from its mouth 936 feet. The progress made during the week was somewhat slower than heretofore, and was owing to the more compact condition of the ground passed through. Have continued (jointly with the Mexican Company) the work of making repairs to the main shaft. In the Mexican mine, on the 1465 level, the new upraise is up 30 feet. The top is in a porphyry formation. At the Union shaft on the 900 level the Union Con. and Sierra Nevada joint east crosscut near the north line of the Union mine started from joint north drift, which was run from the joint west drift at a point 1520 feet west of the shaft, has been extended during the week 22 feet; total length 156 feet; face in clay and porphyry, from which there is a small flow of water. In the Andes mine, on the 420 level, west crosscut No. 3 was extended 18 feet; total length 88 feet; formation clay, porphyry and seams of quartz.

In the Best & Belcher mine, on the 900 level, the east crosscut which is being run on the north boundary has been advanced 21 feet, passing through porphyry; total length 413 feet. In the Hale & Norcross mine, on the 1300 level, they have stopped work from the winze, the ore at this point being too narrow and too low in value to warrant extraction. The station on the 1100 level has been repaired, and are now cleaning out and repairing the main south drift, which will be completed to-morrow, and then will resume work in the face of the south drift. In the Kentucky Con. mine, on the 1100 level, the incline raise from the south for an air connection is up 33 feet in quartz with apots

of ore. On the 1200 level the joint lateral drift with the Yellow Jacket running south in the west ledge is on 15 feet; face in gold of milling grade. From the Occidental Con. mine they extracted during the week about 8 tons of ore from the 400 level, of the average assay value of \$40 per ton. The west cresscent on the 400 level has been extended 9 feet; total length 16 feet; face in porphyry.

Potosi.—The south drift on the 450 level has been advanced 28 feet; total length 228 feet; face in porphyry, clay and hnnches of quartz which yield fair assays. The north west drift from the south drift, on the 450 level, has been advanced 30 feet; total length 59 feet; face in porphyry, clay and low-grade quartz. Hays started an npraise from the last named drift, which is up 4 feet; top shows porphyry and quartz which gives fair assays.

Chollar.—Have started a drift north from the stope on the 100 level which is on 24 feet; the face is in porphyry and low-grade quartz. Are running a drift west, 28 feet below the 100 level, which is on 36 feet; face in porphyry. No ore was extracted during the past week. Milled during the week 91 tons and 1600 pounds. On hand at mill none. Shipped to U. S. Mint at Carson 314 pounds of crude bullion.

Bullion.—The west drift from the station, 820 level, Ward shaft, is on 627 feet from the shaft; face in porphyry.

Alpha.—Are yet engaged in retimbering the old Alpha shaft below the 122 level.

Sierra Nevada.—The south lateral drift from the intermediate tunnel has been advanced 7 feet; total length 491 feet; face in hard porphyry. Wa have completed putting in a compressed-air pipe and are now running machine drills. The joint Union Con. east cresscent near north line, from the north drift 1520 feet west of the shaft, 900 level, has been advanced 22 feet; total length 156 feet; face in clay and soft porphyry, from which there is a small flow of water.

Scorpion.—The east cresscent started in the joint north drift on the 900 level from the Union shaft was advanced 13 feet; face is in a favorable looking formation of porphyry, clay and quartz giving low assays; from the present explorations the stratification appears to be running southeast and northwest, with a dip to the southwest.

Devil's Gate District.

A PATINO PROPERTY.—Enterprise, March 18: Harry Brown made a recent run of 21 tons of ore from the Sonthend mine in Devil's Gate district. The gross bullion proceeds of the run were \$1162.49, or an average of a little more than \$55 a ton. Of this yield \$643.33 was gold and \$514.16 was silver. The net proceeds of the run were \$371.82. The amount of silver in the ore from the Sonthend is something unusual in that district, where, with the exception of the Haywood, the ore is almost exclusively gold-bearing. The Sonthend location is controlled by F. A. Bierke, who leases it on a royalty. The vein from which this ore was extracted is over five feet in width, of which 18 inches is pay. The property is worked through a tunnel 1000 feet in length, which cut the vein at a depth of 200 feet below the surface. There is a large amount of ore uncovered in the tunnel, and the fact that the vein carries such a large percentage of silver is considered an indication of its extending downward to a much greater depth than the tunnel level.

Taylor's mill is about to begin dropping its stamps on another batch of ore from the Oest mine, and the cleanup for the current month, it is intimated by outside parties, will exceed \$20,000. The ore from the Oest is almost exclusively gold-bearing.

The Haywood continues to be a steady ore-producer. The ore, as stated above, contains a percentage of silver; and, although not as high in grade as that from the Oest, it is still paying a good margin above the cost of extraction.

Ferguson District.

A MILL CONTRACT.—Pioche Record: The Magnolia management has contracted with Johnny Ferguson of the Hiko mill for 800 tons of ore, and teams for hauling are in demand. This means that the treatment at the mill is satisfactory, despite the rumors to the contrary which of late have been circulated.

Having ceased ore shipments from the Monitor, Messrs. Reeves, Ellis and Wilson will complete their 500-ton contract with the Bullionville Company with ore from the April Fool and Junho mines. There is a good lot out at the April Fool claim already, but a few men may be put to work on each property.

Silver Star District.

THE NEW GOLD MINES.—Walker Lake Bulletin, March 14: The mines are about 33 miles southeast of Hawthorne and are easily accessible, either from here or any railroad station between this place and Belleville. The main camp is eight miles from Soda Springs and four miles from the Garfield mill, and east of the old Excelsior mine about five miles.

Thirty years ago the Excelsior mine was worked for silver by residents of Anrora. But in those days prospectors were in search of silver only, and quartz that did not show the white metal was passed by unnoticed.

It is doubtful if a miner's pick was ever stuck in the ground now being prospected prior to last September, when a company consisting of W. J. Douglass, Dan Robb, George Fottler, Dan Bowen, Thos. Pepper and E. Grassie, was organized in Sodaville to prospect the surrounding country.

In September last, gold quartz was found on the claim now known as the Dnke. Surface indications were followed east and west, the ledge being plainly visible for a distance of two miles. Subsequent exploration shows that the ledge runs for a distance of four miles and locations have been made for that distance, and yet the end has not been found. From the location of Charles Ganong on the east to that of Fleming & Grassie on the west is over four

miles, and there is an unbroken line of locations connecting them.

The first mine visited was the Orphan Boy of Douglass & Co. There is a tunnel in 64 feet and an incline down about 20 feet. The ledge is a strong and a well-defined one, two feet wide, and the ore assays from \$25 to \$35. There are about 15 tons of ore on the dump. The hanging and foot walls are porphyry.

Hard Scabbie.—This mine is parallel to the Orphan Boy, and is the property of Ed. Brown. There is an excavation on this ground about 20 feet deep, 8 feet wide and 6 feet high, and everything carries gold. Out of the hole described about 40 tons of ore were taken. Mr. Douglass, who is a practical assayer, has made assays of this ore, and he places the average value of it at \$50 per ton. There are no walls here—ore over head, ore under foot and ore on both sides of the miner.

New Party.—This mine is an extension of the Hard Scabbie. An incline 20 feet deep shows a big ledge of \$5 to \$20 ore. Union canyon runs through this location, and where the ledge crosses the ravine a mass of quartz croppings 12 to 15 feet high stares the visitor in the face.

Excitement.—This mine is a westerly extension of the New Party. The same ledge of fine quartz is plainly seen clear through the claim. There are several other ledges exposed on this ground. No development work has been done here as yet, although the float pans well.

Dnke.—This mine is where gold was first found. An incline 20 feet deep exposes a strong ledge, which pans \$5 to \$10.

Fottler.—This mine is across Robb's ridge on the east side, facing Garfield. Here is a ledge the exact width of which is not yet known. Five feet of ore exposed pans about \$15.

Deluvia.—This mine is the property of Grassie & Pedrazzi. A tunnel in 45 feet shows a strong ledge which is placed at \$15, although samples tested at Hawthorne were of much lower grade. There are 15 tons on the dump.

Julia.—Fleming & Grassie have a good, well-defined ledge two feet wide exposed here. A tunnel of 15 feet and an incline of 10 feet is the extent of the work done. About 12 tons of good grade ore are on the dump.

Dolly.—A strong ledge of \$10 to \$15 ore is exposed in three different cuts, none of which is out of daylight.

Donlop and Truman have a tunnel in 50 feet. For a while the ledge was running flat and was of poor grade, but in the face last Thursday it took a sharp downward pitch and the grade of ore was much improved.

Hard Luck.—Douglass & Co. have a tunnel in 60 feet and a drift 35 feet on the ledge. A big pile of ore is on the dump which Mr. Douglass estimates to be worth \$13 per ton.

Gem.—This mine is the property of Robert Stewart and J. P. Harrington. An incline eight feet deep shows a vein of lively quartz. The gold on this claim is much coarser than that on those above described. A second cut exposes a foot of quartz which prospects well in free gold, and the sulphurets of the same are rich.

The mines mentioned are all upon which any work has been done, although each claim-owner has dug sufficiently to show that he is on the ledge.

Robert Webster, A. W. Curtis, James Lothrop, Charles Ganong, John Obendorf, Hank Hof, C. A. Howard, Col. Cutting, Hill Bros., John Berger, John Maney and Frank Robbins have locations.

All the indications point to this being a busy camp ere long. If the ledges now being worked "go down" and hold as good grade as now, it will be as big a camp as the State ever produced. This will be considered a bold assertion, but all the appearances warrant it. The ledges are large. The grade of ore is good; it is gold ore. There is water and wood on the ground. The camp is within a few miles of the railroad and, in fact, it has every conceivable advantage.

ARIZONA.

CYANIDE AT TOMBSTONE.—Prospector, March 14: At the West Side mine Mr. Eltonhead is at work with his electro-cyanide experiments.

He is running through a batch of screenings from a manganese dump that assayed 13 ounces silver per ton, from which he is extracting and precipitating 90 per cent at a cost of less than \$2 per ton. To obliterate the technical language from the description of the process, it is about this way: A box ten by five feet is divided into four equal parts by three planes running lengthwise, making what might be termed four troughs. Quicksilver covers the bottom of these troughs to the depth of a quarter of an inch. The solution, after passing through the screenings in a tank adjacent to the troughs, is conveyed through a pipe to one end of one of the troughs where it passes down over the quicksilver, around through an aperture into the next trough, then to the next and then the next until it has passed through each trough and through an outlet into a barrel. The solution is about a half inch deep over the quicksilver at all times. The quicksilver is charged with electricity by a dynamo, and, when thus charged, precipitates the gold and silver, which form an amalgam the same as by the ordinary process of milling. About eight volts are all that is required to produce the necessary electric current. The present work is only experimental. Application for patents has been made. Mr. Eltonhead will test a shipment of ore from Cripple Creek, which is on the way at the present time. With the small concern at his command, he can treat 25 tons of solution in 12 hours. From 100 to 200 tons of ore can be treated before it is necessary to make a clean-up. This depends of course on the richness of the ore. Mr. Taylor, of the Grand Central Co., who will be with the new owners of the Congress mine, was present this morning and was much enthused over the

working of the process. It is probable that experiments will be made with the tailings and also with some of the ore of the Congress by this process at an early day. With gold ores, Mr. Eltonhead has saved 100 per cent.

GALENA VEIN OPENED.—Kingman Miner, March 17: In the lower workings of the Schnylkill mine at Chloride an 18-inch vein of solid galena ore has been opened up by the Southwestern Mining and Smelting Company. The ore runs better in gold than does that from the surface workings.

There are said to be some splendid gold properties in the country embraced in the big bend of the Colorado river. Prospectors who went there from White Hills last summer made many locations, and there is a fair prospect of inducing capital to invest in them.

J. C. McKenzie has bonded from W. F. Grounds a number of valuable gold properties in Mnsic mountain. It is understood that he will try to induce Colorado capital to invest in these mines and erect mills. Water will be taken to the mines from springs in the adjacent mountains.

W. A. Neal has located a ledge on Burro creek that surpasses anything heretofore discovered in that country. The vein is two feet in width and is all ore. It is located on the side of a mountain and pitches or dips with the hill. A tunnel started in 60 feet below the outcrop cut the vein before it was fully under cover. The ledge wherever opened shows the same rich quality of ore, and the lucky owner is hard at work taking it out to send to market. Mr. Neal will make his first shipment to the sampler next week.

IDAHO.

MONTHLY STATEMENT.—Following is a synopsis of the manager's report of the DeLamar Company for the month of February, 1894:

Tons crushed.....	3,091
Value bullion realized.....	\$70,041 00
Value ore shipped.....	12,090 00
Miscellaneous receipts.....	256 00
Total.....	\$82,387 00
Expenses.....	36,197 00
Estimated profit.....	\$46,190 00

OREGON.

GOOD NUGGET.—Rogue River Courier: Holcombe & Robinson are running a paying placer on upper Jump-off-Joe. Last week a nugget was picked up which weighed \$62. The week previous one was uncovered valued at \$74.

Lister, Calvert & Holyoke are developing a promising claim near by. They are preparing to ditch and pipe in time for next season's water.

Bailey & Fargnhar have their new mill almost ready for crushing at the Mountain Lion on Mission Flat. The roads between the Rogue River bridge at the foot of Sixth street have been badly cut up by hauling the heavy plant over them. The teamsters had a tough time miring down and digging out, the sand which was peppered over the highway last fall having done nothing further than to make freighters swear.

Hall & Beck are working seven men on their placer and quartz mines on Louse creek, eight miles from this city. M. F. Hall was in town Tuesday and exhibited a \$54 nugget, which was washed in sight by one of his two giants. Several smaller nuggets were uncovered previously, but no note is taken of small things at the Hall & Beck mine. They are also driving a tunnel on their quartz ledge which proves to be the source of big nuggets for the placer below.

Messrs. Smith & Pierce have a bonanza within two miles of Gold Hill. They are going down on a ten-foot ledge of rich rock and have a splendid stamp-mill proposition.

Clark & Son of Leland are cleaning \$1 an hour off their two-stamp Tremaine mill within four miles of Gold Hill. This is pretty good wages for three men.

The Hammersmith suit has been settled, and the original locator will take possession of the valuable property on the 22d inst. Digging and crushing will proceed without stoppage.

BRITISH COLUMBIA.

ON THE QUESNELLE RIVER.—John B. Hobson, formerly well known in California as a hydraulic miner in Placer county, is manager of gold mines in British Columbia that are owned by the Canadian Pacific railroad men.

The mines are some sixty miles east of Fraser river, the northerly one being located near Quesnelle Forks, on the Quesnelle river, and the other on Horse Fly creek.

A number of Chinese have been working the gravel for several years past in the primitive fashion of the forty-miners, and have taken out large quantities of gold. It remained for the present owners of the mines to discover their great value. Mr. Hobson says that from the drifting done by some ten or twelve men under his direction last summer he is prepared to believe that the mines will exceed anything of the kind California ever saw. A large and costly hydraulic plant is being established.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

Double Acting Plunger.

Wm. Nance of Grass Valley, Cal., directs attention in another column to the reduction in the weight of pumping machinery, a matter of importance to mine-owners generally, and especially to those working mines far away from a railway.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

WASHING MACHINE.—Joel S. Blood, Houghton, Washington. No. 516,428. Dated March 13, 1894. This machine is an improved form of that type in which a connected plunger and presser are caused to reciprocate within a casing which is provided with a bottom passage through which the water circulates by the action of the plunger. The ends of the casing slope inwardly, to provide for a better circulation of the water. A space or compartment for soaking the clothes is provided in one end of the casing. The plunger has a valve which avoids back pressure. A sliding cover is adapted to inclose the casing while in operation. These several improvements, together with some minor ones, serve to make the whole machine complete and effective.

CAR COUPLING.—David J. Stevenson, Bakersfield, Cal., assignor, by direct and mesne assignments, to John M. Keith of same place. No. 516,457. Dated March 13, 1894. This device belongs to that class in which the link and pin are automatically coupled through the agency of spring-controlled slides within the drawhead, which are actuated by the entering link to lift a spring-controlled lever arm which carries the pin. The present invention is an improvement on a prior patent to the same inventor, and consists generally in the changing and modifying of the several parts which, as a whole, result in general simplicity and effectiveness, and provide a perfect automatically coupling device of the ordinary link-and-pin kind.

GRAVEL OR DIRT WAGON.—Arthur W. Coats and James Bartlett, Ukiah, Cal. No. 516,564. Dated March 13, 1894. This wagon consists essentially of a bed having its bottom composed of a hinged, swinging, horizontal section; one or more hinged, swinging, normally inclined sections; means for locking and relieving the horizontal section and connections from the horizontal section, whereby its dropping movement serves to swing the inclined section to a greater inclination. The object is to provide a simple and effective self-dumping wagon which can, when necessary, be converted into an ordinary wagon with a common bed.

JAIL CONSTRUCTION.—David Salfeld and Hermann Kohlberg, San Francisco. No. 516,450. Dated March 13, 1894. The object of this invention is to construct a building which will be specially applicable for jails, prisons and buildings where it is desirable to incarcerate persons to retain them safely under constant surveillance and at the same time keep them separate from and invisible to each other. It is of great importance in the construction of jails to so situate the inmates as to be subject to the vigilance of the keepers at all times, and also to separate them from each other so that they can have little or no communication, as well as to prevent the inmates already in the cells from having a knowledge of others that may be brought in from time to time. In this invention a circular construction is adopted, having a central guard-room, an intermediate open space exterior to it, and a cell space forming any desirable portion of a circle exterior to the intermediate space. The cells and the intermediate passages formed in this portion have their walls in radial lines from the center, so that each passage is visible, and the doors opening into the cells are at opposite ends of the passages and so constructed that no sight or communication between the inmates can take place. The interior ends of the passages between the cells may, if desired, all be closed whenever new prisoners are to be brought in, so that no sight or knowledge of them can be obtained from inmates already there.

CAN-SOLDERING MACHINE.—Mathias Jensen, Astoria, Oregon; assignor of one-half to the Jensen Can-Filling Machine Company. No. 516,308. Dated March 13, 1894. This invention relates to a novel means for applying solder to the longitudinal side seams of cans. It consists of a roller, journaled to rotate longitudinally within the solder bath and beneath the cans, which are moved along above and parallel with this roller with the longitudinal seams at the lowest point, so that the rotation of the roller continually carries up a body of molten solder and applies it to the seams while the cans are passing above the roller.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MARCH 13, 1893.

- 516,292.—VOTING BOOTH.—E. F. Barry, Elk Grove, Cal.
- 516,425.—EASEL.—Hattie F. Beecher, Port Townsend, Wash.
- 516,423.—FEED WATER HEATER.—J. B. Bell, Troutdale, Or.
- 516,428.—WASHING MACHINE.—J. S. Blood, Houghton, Wash.
- 516,261.—PROPAGATOR.—A. H. Carpenter, Stockton, Cal.
- 516,564.—DIRT WAGON.—Coats & Bartlett, Ukiah, Cal.
- 516,298.—DYNAMO.—F. J. Cronch, Junction City, Or.
- 516,592.—DOOR LOCK.—W. T. W. Curi, Los Angeles, Cal.
- 516,501.—PROGRAMME HOLDER.—E. Douglas, Hanford, Cal.
- 518,303.—TOBACCO JAR.—M. Goldwater, Prescott, A. T.
- 516,437.—FRUIT CARRIER.—W. E. Howell, Los Angeles, Cal.
- 518,308.—CAN SOLDERING MACHINE.—M. Jensen, Astoria, Or.
- 516,440.—SEPARATOR.—R. W. Jessup, Los Angeles, Cal.
- 516,442.—BLOWING ENGINE.—C. A. Klotz, Vallejo, Cal.
- 516,450.—JAILS.—Salfeld & Kohlberg, S. F.
- 516,457.—CAR COUPLING.—D. J. Stevenson, Bakersfield, Cal.
- 516,557.—DIRT WAGON.—M. Stone, San Diego, Cal.
- 516,239.—SAFETY PROTECTOR.—C. F. A. Sturte, S. F.
- 518,240.—WINDOW PROTECTOR.—C. F. A. Sturte, S. F.

Market Reports.

The Markets.

SAN FRANCISCO, March 22, 1894.

The silver market has shown but little change during the week. It might have been expected that the passage of the seigniorage bill would have had some effect, but the absolute lack of information as to whether the President will or will not sign, have made it questionable if it will become a law, and there has been neither an upward nor downward tendency. The market is simply waiting. It is not known at this writing what the President intends to do. Opinion is about equally divided. To-day's New York quotation is 59 3/4c.

American Copper Product.

The New York Engineering and Mining Journal reports the copper product of the United States for 1893 as follows:

Montana product, the.....	160,092,711
Michigan.....	113,742,140
Arizona.....	43,717,423
Other Domestic Sources.....	15,813,235

Total domestic.....	332,585,500
From Imported ores.....	7,233,387

Total.....	339,808,887
Stock January 1, 1893.....	56,000,000

Total.....	386,308,887
Exports.....	130,066,880

Total.....	256,242,007
Imports.....	5,538,690

Available supply.....	211,778,697
-----------------------	-------------

The quantity allowed for consumption in 1892 was 265,380,000 pounds. It ought to have been larger in 1893, but it could not have been much over 200,000,000 pounds, if the supply be correctly reported as above. The domestic product for 1892, as given by the same authority, was 325,180,000 pounds, while the quantity extracted from foreign ores was 10,200,000 pounds, but the exports for that year were only 90,000,000 pounds. The product for 1891 was 286,100,000 pounds, and 11,500,000 pounds were taken from foreign ores. For the past two years Montana has led all other sources in the quantity produced, though the total from that State last year was 14,000,000 pounds less than in 1892.

Lead.

Lead shows more firmness, being possibly influenced by the report of the Senate Committee fixing an absolute tariff charge of 3/4c per pound on lead and lead ores.

New York Prices.

NEW YORK, March 22.—Following are the closing prices for the week:

J. F. CROSETT, Commission Mining Agency,
628 Sacramento St., San Francisco, Cal.
Buy and Sell Meritorious Mining Properties. I have orders for Income-Paying Mines at the present time. Have also some good properties for sale. I want more mines to offer to purchasers and also desire more purchasers to examine properties I have to offer. Correspondence solicited.

Mining Share Market.

SAN FRANCISCO, March 22, 1894.

The San Francisco Stock and Exchange Board yesterday endorsed an amendment to the Constitution permitting fluctuations of one cent per share in all mining stocks upon the list which sell below \$1 per share. Heretofore no change of less than five cents was allowed. The new rule went into effect immediately after the executive session was over, which was at 10:15 A. M. At the start it looks to many dealers as if this new departure at the San Francisco Stock and Exchange Board is designed to take away much of the business of the Pacific Board brokers. At the Pacific Board fluctuations of one cent per share in stocks selling below \$1 have always been permitted.

The Comstock market showed gains during last week, but this week a much weaker tone and lower prices have prevailed. During the week Consolidated California and Virginia advanced from \$2.80 to \$3.45; Ophir from \$2.35 to \$2.75; Mexican from \$1.35 to \$1.65; Best & Belcher from \$1.55 to \$1.80; Potosi from 70 cents to \$1; Yellow Jacket from 60 to 80 cents; Belcher from 60 to 90 cents; and Crown Point from 40 to 65 cents. Our quotations to-day show to what figures the various stocks have receded.

Coast Industrial Notes.

—The total value of breadstuffs exported from Pacific Coast points during February, 1894, was \$1,606,882 against \$2,945,327 for the same month last year. The total for cattle and hogs and their products, together with oleomargarine and dairy products, was \$45,140, as against \$59,531 for the same month last year.

—The steamer City of Puebla, which broke down off Cape Flattery and was towed back to Port Townsend by the tug Wanderer, was libeled by the Puget Sound Tugboat Company for \$100,000. The owners of the Puebla offered the tug company \$1600, which was refused, the amount demanded being \$30,000. The Puebla will furnish bonds.

—A contract has just been entered into between the Pacific Improvement Company and Thomas Day & Sons. For the sum of \$46,000 the latter agree to build the car-house for the new electric line on the east line of Mission street, opposite Twenty-ninth, within 100 working days. The contract for building the power house for the electric systems of the Market-street Railway Company at the junction of Eleventh, Bryant and Channel streets was also agreed to. The poles have been erected nearly to the Five Mile House and a portion of the wires also stretched.

—A dispatch from San Diego says that Herbert L. Emery has sold his ranch in Pine Valley to the Pine Valley Consolidated Water and Land Company, together with the well-known Pine Valley reservoir site and water rights, where surveyors have reported that a perfect title exists for a dam that is capable of impounding eight billion gallons of water, two billions more than the Sweetwater reservoir. The Pine Valley Company, which is composed of Emery, his brother, General Eli H. Murray and others, is about to make arrangements to develop water rights on the land and to take advan-

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with the shaft. SPECIAL CONSTRUCTION OF STEEL only one-eighth part the weight of the old pump. Works with 10 per cent less power. First outlay one-third the cost of the old pump. Has been tested a year and proved to work satisfactorily in every respect. GLAND OF STUFFING-BOX TIGHTENED AND ROD LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING OR BUCKET PUMP.

Bucket, clack and clack-acting changed under water. Bucket lasts six times as long as the old bucket, often saving expense of putting down another pump, especially in jack-hack pumps, where bucket and clack cannot be changed under water. Special attention is called to the self-tightening stuffing-box and new bucket which obviates the expense and delay of frequently dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, Cal.

tage of the reservoir site. The dam as proposed to be built will be 125 feet in height, but it can be extended to 150 feet if desirable. The reservoir site is an oval valley containing eight miles of land, ending in a narrow canyon with steep sides, and level and continuous bedrock, so far as inspected.

—Representative Loud has been making a strong effort to secure an appropriation of \$5000 for the survey of the harbor of San Francisco. Chairman Sayers of the Appropriation Committee was unwilling to grant this amount of money, but now he has made a proposition to Loud that he will direct the superintendent of the Geodetic Survey to make this survey and this would do away with the necessity of any special appropriation. Loud immediately acceded to this proposition and the survey will be made. Loud has also succeeded in getting the promise of \$10,000 for a coast and pilot chart of the whole Pacific Coast, to be issued monthly. Many petitions have been sent to Congress from California to secure the publication of this chart.

THE ORIENTAL GAS ENGINE

IS THE BEST, because it combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosion. No licensed engineer at a high salary needed to operate it. Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from Thomas A. Ide son in the Spanish Hill Gravel Mine, near Placerville, El Dorado Co., to deposit tailings behind a dam on the bank of Cedar Creek; from the El Dorado Water & Deep Gravel Mining Co. in the Spanish Hill Hydraulic Mine, near Placerville, to deposit tailings behind brush dams in Spanish Ravine; from Pascoe & Gruben in the Eureka Hydraulic Mine, near Placerville, to deposit tailings behind a brush dam on a flat; from John Blair et al. in the Mitchell Hydraulic Mine, near Placerville, to deposit tailings behind a rock dam in Spanish Ravine; from James Hackett in the Oriental & Thore Mine, near Rough & Ready, Nevada Co., to deposit tailings behind dams on the side hill and in a ravine; from E. B. Jacks in the Badger Hill Placer Mine, near Spanish Ranch, Plumas Co., to deposit tailings behind a rock dam in Spanish Creek; and from Tucker & Brown in the Grub Flat Placer Mine, near Spanish Ranch, to deposit tailings in an old hydraulic pit, gives notice that a meeting will be held at Room No. 32, Flood Building, San Francisco, Cal., March 27th, 1894, at 1:30 P. M.

Assessment Notices.

SUPERIOR MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Placerville, El Dorado County, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 13th day of March, 1894, an assessment (No. 1) of Twenty Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, Room 17, 318 Fine street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23rd day of April, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 14th day of May, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors. R. W. HEATH, Secretary.

Practical Hydraulics.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is especially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated: General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Opening; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc. Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Office of General Manager,
P. O. Address, South Riverside, San Bernardino Co., Cal.
CAJALCO, Dec. 18, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
I am, my Dear Sirs, Yours faithfully,
S. HARRIS, Manager.

Price of 4-foot wide Plain Belt Frue Vanner.....\$550, f. o. b.
" " Improved Belt Frue Vanner 800, f. o. b.

Combination Process.

The combination process is the method of treating gold and silver-bearing ores, by the application of the concentration and amalgamation process combined, and is especially adapted to ores that are not free milling.

It is not an experimental nor new process, but simply a combination of well-known and successful methods in daily operation throughout the mining sections of the country.

The mill which we illustrate herewith—made by the Union Iron Works—is designed to treat refractory ores

mines, and for such ores as we have described the combination process is not only cheap but a most practical method of reduction.

A COMPANY of Kansas City men, whose personnel is not given, has arrived at Oroville, Butte county, for the purpose of engaging in a river-mining scheme by a new process, whose nature is not explained. The members of the company are said to be men of large means who have thoroughly investigated the mining outlook and believe they have a bonanza. It is their intention to place the machinery in position as soon as possible. The land

the product of the United States will show an increase of \$4,000,000. There is also a gain of \$500,000 from Australia and \$500,000 from Russia. There is some slight shrinkage in other countries. The greatest relative gain in the United States comes from Colorado, the prominent contributors to which are the recently opened mines at Cripple Creek.

At a meeting of the Debris Commission on Tuesday, permits for hydraulic mining were issued to the following persons: Daniel W. Alhert for the Union mine and W. W. Lemmon for the Conduit Ravine mine. Both

TWENTY STAMP MILL, COMBINATION PROCESS.

carrying gold and silver associated with the baser metals, such as iron and copper pyrites, lead, zinc, antimony, etc.

The ore is first passed through the rock breaker or crusher into the ore bins, from whence it passes automatically into the self-feeders, which deliver it as required into the mortars of the battery. Here it is crushed wet and discharged through the battery screens upon silver-plated copper plates, which extract the free gold contained in the ore. From these plates it passes on to the first set of concentrators, where the heavier base metals are eliminated. The tailings from these machines then pass on to the second set of concentrators, where final concentration takes place, eliminating the zinc, antimony, etc. The tailings from this last set of machines, containing the sulphides, chlorides and fine gold, which can not be concentrated, pass into the settling tanks, where, after the surplus water is drawn from the pulp, it is shoveled into the pans, amalgamated, discharged into the settlers, and the amalgam strained, retorted and melted in the usual manner.

The concentrates obtained can be disposed of as may be best suited to the commercial conditions governing each particular case.

This process is being adopted by many of the largest

mines, and for such ores as we have described the combination process is not only cheap but a most practical method of reduction. Several river-mining plants have been placed in operation below Oroville during the past twenty years, but none of them have been very successful. The *Register*, in reporting the project, says it knows nothing of the merits of the contemplated plant, how the ground will be worked, or what the experience of the managers may be. But the land along the river banks is rich in gold, and if any plant was placed so as to drain the mines and get down to bedrock a great deal of gold could be extracted. About the bed of the river there is not so much confidence.

THE Director of the Mint at Washington has issued a preliminary statement of the gold product of the world for the calendar year of 1893. It shows a large increase over that for any previous year. It will be remembered that the same authority placed the gold product of the world for the calendar year of 1892 at \$138,861,000. It is now thought the product for 1893 will approximate \$150,000,000, or fully \$11,000,000 more than in the previous year. The greatest gain is from South Africa, whose product is placed at \$6,000,000 more than in 1892. It is also estimated that

mines are located near Brownsville, Yuba county. A permit was also granted R. M. Moorer for the Kelly Hill mine, in Butte county. The following mines were granted permits to construct dams: Spanish Hill hydraulic mine, Spanish Hill gravel mine and Mitchell hydraulic mine, all being located near Placerville. The Polar Star mine, in Dutch Flat, reported closing down, having accomplished all it can with its present impounding works. It will soon make application for permission to increase its ravine and dam and then resume work. The Hustler mine, near Cherokee, asked permission to begin operation, although its dam is not completed to its full height. The request was denied.

MR. JAMES SPIERS' communication on industrial education, found on page 206 of this issue, is a practical view of an interesting subject by a practical man. It advances sound views in a clear and convincing manner, and will afford much food for reflection. Mr. Spiers believes in theoretical education, but he believes more in the value of actual education—in hand work as well as head work. The two combined give us our most expert mechanics and engineers. One is essential to the other.

THE low price of silver can hardly be regarded as a very desirable thing; still, it seems to have opened up a new avenue of industry to a number of very enterprising citizens of Omaha. It is no more nor less than the coining of silver dollars with precisely the same amount of silver and alloy as are contained in genuine dollars. The workmanship is reported to be so thorough as to deceive even experts. The profit to the minters of course lies in the seigniorage, which is over fifty cents. The government officers do not regard the new enterprise with favor, and are, in fact, hunting for the promoters for the purpose of taking them in custody.

THE sale of the Poorman mine in the Cœur d'Alenes for \$500,000, and the resumption of work on the Gem, are hopeful signs for lead and silver miners. It is not probable that so large an investment would be made unless the investors had strong grounds for believing silver or lead, or both, have seen their worst days. The Poorman mine is remarkable in many respects. It was located nearly ten years ago. It adjoins the Tiger, owned by S. S. Glidden, and is across the canyon from it. Scott Macdonald, now a citizen of Wallace, was the original locator. For three years it was involved in litigation arising from a conflict of boundary lines. The suit was finally compromised and the recent owners bought it for \$80,000. It has paid \$360,000 in dividends since then. That was clear of all expenses, and it is the most extensively developed mine in the Cœur d'Alenes. Patay Clark, who is now in Helena, has been manager ever since the purchase by his company. It has nearly four miles of underground work, besides extensive hoisting machinery and pumps and a concentrator. During flush times it paid good wages to 250 men.

THE Superior Court of Calaveras county has just rendered a decision of interest to miners, on the subject of relocation, in the case of Ayre & Danielson vs. O'Neil. The facts are substantially that plaintiff located a claim in 1880, and performed no assessment work until December, 1891, performing \$80 then, \$45 in January, 1892, and \$90 in December, 1892. Defendant relocated the property in July, 1892. The court held that it is a matter of no consequence to the case in question whether or not the annual assessment work was done between 1880 and 1892, so long as the original location was valid and the locators resumed work upon the mine before it was relocated; that the ownership of the mine was in the original locators until it had been relocated by other parties, and from the fact that they had resumed labor on the mine prior to July, 1892, and before any other parties had acquired title to the land, they were entitled to the whole of 1892 in which to do the amount of assessment work. Judgment is therefore given for the plaintiffs. After all the real issue was the question of fact. If the facts are as stated, the decision is undoubtedly in conformance with well-established and well-understood law.

Enforcing the Caminetti Law.

The enforcement of the penal provisions of the Caminetti law is at this time giving the Anti-Debris Association much concern; and it is proper to say that the miners themselves do not view the situation with entire satisfaction and are anxious for the settlement of certain questions of law which are in dispute. The trouble arises partly out of the controversy as to the proper method by which violators of the law are to be brought to justice, and partly out of lack of funds by the United States authorities to enter upon any campaign against illegal mining. It is worth while to recite the facts which have brought about the present situation:

Thursday of last week W. T. Phipps, president and manager of the Anti-Debris Association, accompanied by Attorney Devlin of Sacramento and Nathan E. Boyd, an agent of the association, called upon District Attorney C. A. Garter and requested him to issue warrants for the arrest of Ah You and Ah Joe, who have been mining in the county of Nevada by the hydraulic process. They alleged that the Chinese, on March 17, 1894, in the county of Nevada, wilfully, wrongfully and unlawfully mined by the hydraulic process within the meaning of the act of Congress entitled "An act to create the California Debris Commission and regulate hydraulic mining in the State of California."

It is charged that in the Red Diamond mine, located 14 miles east of Nevada City, the unlawful work was done. Earth and gravel were washed from their natural bank with a monitor and nozzle and discharged into Deer creek, which is adjacent to the mine. Deer creek conveyed the debris into Yuba river and thence into the Sacramento river, obstructing the streams by the formation of bars and interfering with the travel of vessels.

Mr. Garter listened to the complaints of the gentlemen and then informed them that he must decline to grant their request. A number of reasons were given by the attorney for his refusal, but as he declined to be interviewed upon the subject all of them could not be learned. The principal reason for declining to issue warrants is known to be because there is no money on hand with which to pay jurors and witnesses who are summoned to the United States courts.

If arrests are made for violations of the Caminetti law there will be a large number of them and such course will require the outlay of a considerable sum of money. Owing to the lack of funds the United States judges of this district have given the District Attorney to understand that he must not push the cases now on hand until another appropriation has been received.

For that reason, and also because the District Attorney is in doubt as to his right to proceed in the manner proposed by the Anti-Debris Association, he declined to order the warrants, but agreed to lay the matter before Attorney-General Olney for his decision. Mr. Boyd then went before United States Commissioner Heacock and swore to a complaint against the two Chinese, charging them with the violation of law already stated.

At last accounts the Chinamen had not been arrested, and it was not possible to tell just how far or exactly in what manner the anti-debris people propose to push the campaign. It seems to be clear, however, that they have decided to ignore the Debris Commission and its authority altogether, pursuing as closely as possible the precedents laid down some years ago when direct appeal was made to the courts. It would seem, however, that even from the point of view of the anti-debris people, the wise policy would be to lay their complaint before the Debris Commission and exhaust every resource, in the manner laid down by the Caminetti law, to secure its enforcement. It is clearly the duty of the commissioners to look after violations of the law, as witness the following section:

SECTION 19.—That an intentional violation on the part of a mine owner or owners, company or corporation, or the agents or employees of either, of the conditions of the order granted pursuant to Section 13, or such modifications thereof as may have been made by said Commission, shall work a forfeiture of the privileges thereby conferred, and upon notice being served by the order of said commissioner upon said owner or owners, work shall immediately cease. Said Commission shall take necessary steps to enforce its orders in case of the failure, neglect or refusal of such owner or owners to comply therewith, or in the event of any person or persons, company or corporation working by said process in said territory contrary to law.

It may be claimed that the Debris Commission has no funds to enforce the law, and appeal to them would be in vain. But it would be well enough for the Anti-Debris Association to obtain an official utterance from the Commission, proceeding in the manner required by law. As it is now, they are in the position of asking the enforcement of one provision of the law and desiring to avoid the operation of another. They demand that certain miners be punished for violating a provision which suits them, and decline to obey a provision which does not suit them. If all laws were observed in the manner pursued by these

people who have long demanded that the law make them secure in the enjoyment of their property, anarchy would result.

The Hoke Smith Decision.

THE PRESS recently referred to a decision of the Secretary of the Interior relative to placer locations, in effect requiring that discoveries must be made on each 20-acre tract in order to hold it. Says the Secretary:

In my opinion there must be a discovery upon each 20-acre tract included in a placer location of 160 acres, and a location made of that amount of land upon a single discovery is void, except as to the 20 acres immediately surrounding it. To constitute the law otherwise is to open the doorway for the appropriation of the public lands that would be doing great violence to the intent and meaning of the mining law.

The decision seems to contain all the bad law and injustice to the miners we feared. If allowed to stand, it must do serious damage to placer miners, and will render it very difficult, and even impossible in many instances, to carry on operations on a sufficient scale to make them profitable. The Anti-Debris Association has found an unexpected friend in the amiable Secretary of the Interior who seems to think it unnecessary to understand conditions and precedents in order to interpret law.

This remarkable decision emphasizes the justice of the plea of the miners for stronger and more definite recognition in the Government administration. The Secretary of the Interior is Mr. Hoke Smith, who hails from Georgia, just about as far remote from the great mining center of the United States as it is possible to get and not fall into the Gulf of Mexico. Doubtless the decision was written by some fourth-rate clerk who was never outside the District of Columbia, and who thinks a placer mine is some sort or device established solely by a beneficent Creator for litigation purposes, thus giving employment to an impecunious set of government interpreters who like necessity know no law; or, if they do, understand not its relation to right. It is regrettable that Mr. Hoke Smith has been compelled to father a decision of whose merits he knows nothing; and it is also regrettable that controversies which come before his department are not confined to the merits of watermelons or some other Georgia product, about which he may be presumed to have authoritative knowledge.

The Counties at the Fair.

It is the purpose of the PRESS to give adequate notice, during the continuance of the Midwinter Fair, not only of the exhibits of the various counties, but of the various deserving kindred displays of mechanical and metallurgical appliances now in the Mechanic Arts building. The notices of the county exhibits which have already appeared have excited favorable attention in the various counties as being fair, complete and accurate, and other articles will be up to standard. It should be distinctly understood that no charge is made for these notices. It is both the pleasure and the duty of the PRESS to promote the mining interest by all means in its power, and it conceives that it would not be furthering that end if it did not furnish reliable and timely information at all times concerning mines and mining. It ought to be said here that any so-called mining paper which has any other policy is not fulfilling a laudable mission. Such papers have no standing and less influence. Their circulation is confined to the few copies which the counties which are "written up" purchase and distribute. Counties or exhibitors who refuse to pay are ignored. The articles are inspired by no motive except that of gain, and are, as a rule, incorrect, unreliable and unconvincing. They do more harm than good. As a case in point it may be mentioned that an obscure paper is now attempting to "work" the various counties by methods which may properly be termed blackmail. It is gratifying to know that it has not met with success.

ORDERS were posted at the Gold Bank, Forbestown, last Saturday, announcing that the Sunday shifts would be suspended and no more work would be done in the mine on Sunday hereafter than was absolutely necessary. Also that the change of shifts from day to night would be made every week instead of fortnightly as heretofore. This order does not apply to the millmen, only so far as the weekly change is concerned.

THE first bar of bullion produced in this section from Ferguson district ores was shaped at the Hiko mill on the 28th ultimo, its value being a little over \$3000, says the Pioche Lode. The following day the Condor mill retorted a bar valued at about \$14,000, and yesterday the Hiko mill retorted another bar valued at about the same as the first. This makes a total product of about \$20,000.

THE expected happened, and the President to-day (Thursday) sent to Congress his veto of the Bland seigniorage bill.

California Mines at the Midwinter Fair.

Calaveras County.—Calaveras, to which belongs the honor of having the largest producing gold mine in the State, is finely represented at the Midwinter Fair by a display of ores from its working mines, and other natural products, designed to show the varied mineral resources of the county. There are features to the exhibit which are unique, and which attract the favorable comment of many visitors. The essential idea of the collection was to display the character of gold and copper ores, and this plan has been carried out most successfully. Occupying a conspicuous position are two tons of quartz from the famous Utica mine at Angels—a mine more talked about than any other in California during the past two years, and a mine, further, that by actual working results shows that it deserves all its fame. According to authentic report the Utica produced during the year 1893 upwards of \$1,000,000, exceeding the record of the Kennedy in Amador county, the next largest producer by about \$400,000, and surpassing the best California record for 1892 (the Kennedy's) by over \$500,000. It may be said in passing that the Utica is one of the most noticeable instances in mining annals of the successful reopening of an abandoned mine; and, besides, its greatly increased production for 1893 finely illustrates the increased interest in gold mining in California and gives substantial promise for an active and prosperous future for the entire industry. The Utica, which is a consolidation of two or three claims on the same vein on the mother lode, is opened by three shafts, which are down from 500 to 900 feet. Development may be said to be carried on all over the mine. The vein at one point is *eighty feet wide*, probably the largest true ledge in any gold mine in the United States. The quartz varies in value from \$3 to \$60, and is both free milling and sulphureted. Sulphurets, as a rule, run very evenly from \$40 to \$70. At the Utica mill 60 stamps are dropping; at the Stickle, 60 stamps; at the Madison, 40 stamps; making a total of 160 stamps crushing ore for the Utica Company—the largest in California, and, except the Alaska-Treadwell, the largest on the Pacific coast. The ore shown in the Calaveras exhibit is the average ore taken from the mine. It is typical mother-lode quartz.

The second important display is copper ore in its various forms from the Union Copper mine at Copperopolis, and the Campo Seco and Satellite mines at Campo Seco. The Penn Chemical Works are owners of the latter two mines, and their exhibit is designed to show copper from the ore to the ingot, with sulphate, sulphide and carbonate copper ores. Copper cement, from which mineral paint is made, is also shown. As a matter of fact the Penn Chemical Works are now devoting their entire efforts to producing copper cement, no work being done in the mines. Thousands of tons of ore are now on the dump, sufficient for the purposes of the reduction works for some time to come. The display of the Union copper mine is of much the same character, and is alike creditable and interesting. One curious difference in the ores from these two mines—which are doubtless on the same ledge, though 20 miles apart—may be noted. At Campo Seco the ore carries about \$3.50 in gold and 18 ounces of silver to the ton; at the latter there is no trace of the precious metals. The vein at Campo Seco approaches the mother lode, and it is probable that the same influences which deposited gold and silver in the lode were also felt at Campo Seco. From the Copperopolis mine also comes very richly sulphureted ore taken from the Royal Consolidated (formerly the Pine Log) mine. The display of gold ores from this mine, near the Campo Seco district, shows very well the variety of the mineralization of the district.

One interesting display is a collection of quartz from the Carson Creek (Jones) mine, three miles from Angels. It may be remembered that a recent assay of ore from this mine showed the value to be \$30,000 per ton. Of course it is not pretended that this is the average ore, but it appears to be certain that the mine will be remunerative. It has been closed down for quite a long time, but an energetic company now has possession and development is being pushed.

Two very large pieces of crystallized quartz from the McSorley brothers mine attract a deal of attention. One weighs about 100 pounds. They are really very fine specimens, being the largest and among the clearest in the entire mining exhibit.

Seven hundred pounds of quartz from the Lone Star mine and 300 pounds from the Reed & Hillery mine, both in the West Point district and operated by the Hurley Mining Company, are prominently shown. A peculiarity of these ores is the presence of free milling alongside very rebellious ore—so rebellious that it must be smelted. However, the ore is rich, at times running as high as \$600.

Other collections of quartz which are deserving of special mention are to be found in the summary. From the

Moser mine, free-milling rock of a very fine quality is on exhibition. It is said that Gen. Alger of Michigan was especially attracted by this exhibit and asked permission to take back home one of the specimens.

A conglomerate quartz from the Flour Sack mine has excited a good deal of comment among experts. The ore is very rebellious and has to be sacked and sent to Selby's for smelting. The mine is idle now, this method being found too expensive.

An exhibit of gypsum shows the possibilities of Calaveras in that line. It is said to be from a "whole mountain" of gypsum, whose development would probably be remunerative.

Obalk from the Jesus Maria district, Jos. Del Orto owner, is a very pure and clear, and is altogether one of the most attractive specimens shown. Two exhibits of iron ore come from deposits owned by May Bros. and George Blay, in the same district.

Terra cotta clay, from the Campo Seco district, is of fine appearance and is said to have high value. The deposit is being gradually developed by Mr. Wilbur of Stockton, owner of pottery works, who says it is as fine as any that comes from Italy. It is the only display of the kind made by any county. Sandstone from the Campo Seco district may be used for building and ornamental purposes, and gray marble from the O. J. Cantwell quarry, San Andreas district, takes a high polish. Development of this quarry has just begun. White marble of good quality from San Andreas, A. F. Treat owner, is also shown.

A display of tuff stone, by the Campo Seco Building Stone Quarry Co., M. A. Edwards manager, attracts much attention. A part of this exhibit was at the World's Fair.

It ought to be said that the Calaveras exhibit was collected through the efforts of the executive committee appointed by the California Miners Association. They received no financial aid from the county; but, being possessed of a large fund of local patriotism, and being also convinced of the merit of Calaveras mines and the value of a proper display at the fair, they undertook the work. Mr. Foreman individually superintended the installation of the exhibit, and is constantly on hand to point out its special features to the numerous visitors, and he does it with intelligence and a due amount of enthusiasm. With other members of the committee, he is certainly deserving of the praise of Calaveras county miners for the really fine display he has succeeded in making. It is to be hoped that the Supervisor of Calaveras county will yet see their way clear to make an appropriation for the maintenance of the exhibit, and for the addition of other features which would add a great deal to the value.

A summary of the Calaveras exhibit may be found in the following:

Free gold ore from the Lone Star, Reed and Hillery, Utica, Royal Consolidated, Moser, Jacobs, Flour Sack, Mount Timolas, Sandy, Lindner, Robinson, Sparrow Hawk, May Brothers, Venns, Fisher, Blay, Leota and Scotia mines; copper ore from the Union mine at Copperopolis, tuff from the Campo Seco district, quartz crystals from the McSorley mine, gypsum deposit from the Davison mine in the Rich Gulch district, chalk from the Del Orto mine, manganese ore from the May Brothers' mine, gray marble from the Campo quarry and Cantwell quarry, terra cotta clay and sandstone from the Campo Seco district. The Penn Chemical Works has a display of copper in the several stages from the ore to the ingot, including sulphate and carbonate ores, the roasted ore, solution and cement; also ingots of refined and casting brand.

Foundry Notes.

Five Woodbury concentrators have just been sent to Colorado.

The big quartz mill at the Fair, erected by the Joshua Hendy Machine Works, has been put in operation. The mill occupies a corrugated iron building erected for it just opposite the western entrance to the Mechanic Arts building. The complete process of extracting gold from the rock is shown, and it is needless to say that crowds of visitors lingered in the building during the afternoon despite the fact that the roar and pounding of the stamps was almost deafening and disastrous to the nerves. The mill is operated by H. G. Murray, a practical Amador county mining man, and he proposes to run it every afternoon from now on. Gold-bearing quartz is used in demonstrating the process, which makes the exhibit all the more interesting.

A detachment of Royal Marine Artillery, numbering 75, has arrived in Montreal en route to Esquimalt, B. C., where, on arrival, they will be set to work on the new fortifications upon which Great Britain has resolved to expend \$5,000,000. The work will occupy two years and will be carried to completion with all secrecy. The small peninsula between Esquimalt and Victoria harbors is to be made impregnable to attack from the sea and practically so from the land. The fortifications are projected to extend from Point MacAnley all the way to the head of Esquimalt harbor, literally encircling the latter, its navy yard, imperial dry dock, magazines and storehouses. A system of great tunnels will connect the pits and magazines. The guns will be worked on the elevator principle. At intervals tremendous wells are to be built, in which will operate by hydraulic power and electricity large elevators bringing from the ground batteries of artillery and crews to operate them, and sinking with men and guns back into the earth as soon as the guns have been fired.

Sliokens.

The Gem mine in the Cour d'Alenes has resumed, giving employment to 110 men.

Thirty dry washers have been made in Porterville for men who intend to go to the Goler mines in Kern county.

A special to the Salt Lake Tribune from Rock Springs, Wyo., says that a rich vein has been discovered near Lewiston in the South Pass country.

There are strong probabilities that active work will soon be commenced on the property of the Ohio Gold Mining Company, situated on the San Joaquin about five miles up the river from Polasky.

I. W. Willsay, a miner, while prospecting in an old mine, 150 miles from Enreka, Nev., struck a stick of giant powder. The powder exploded, terribly lacerating him. He was taken to Sacramento. He will lose both eyes.

Colonel S. A. Estes, largely interested in mining interests, died suddenly at Salt Lake on Sunday. He came from Montana about a year ago, and was putting up a large copper smelter in Salt Lake.

The Sunree Gold Quartz Mining Company has been incorporated. Principal place of business, San Francisco. Capital stock, \$1,000,000, with E. H. Baxter, George F. Hill, D. J. Halloran, E. T. Baxter and James P. Sweeney of San Francisco as directors.

The prevailing opinion is that John R. Tregloan will be selected superintendent of the Wildman mine, vice John R. Tregloan Sr., resigned. Mr. Tregloan Sr. and his wife expect to take a trip East during the spring, and upon their return will reside in Alameda.

The gold fields of the Rainy Lake district, along the northern boundary of Minnesota, will attract a great crowd of people when spring is fairly opened. The latter part of the trip is made by stage from Tower, on the Vermillion Range, or Mountain Iron, on the Mesaba Range.

Several gold, silver, copper and iron mines near Bozeman, Montana, have just been purchased by George W. Ballou, who represents a syndicate of New York capitalists. The price paid was \$1,000,000. The mines will be extensively developed and large concentrating works will be erected.

The Golden West Mining and Machine Company has been incorporated. Principal place of business, Berkeley. Capital stock, \$1,000,000, with Henry Golsch, Charles Hadlan and C. H. Spear of West Berkeley and William Frey, Fritz J. Kaeser, Arnold Kaeser and R. Kaeser of Sacramento as directors.

President J. P. McBurna of the United Mine-Workers of America has issued a circular calling for the fifth annual convention of the organization to be held at Columbus, commencing April 10. A great strike is said to be contemplated. There are in America 100,000 miners who are attached to the United Mine-Workers' Association.

The gold production in Montana during January and February, and thus far in March is said to be double that of last year, and the prospects are that the production for the entire year will be more than double that of 1893. The silver mines, of course, have closed, but the copper mines are employing the same number of men as formerly, and gold mining has taken care of large numbers of the unemployed.

A dispatch from Albuquerque, N. M., says that phenomenal strikes in the Cochiti mining district have set New Mexico wild, and the prospectors are pouring into Cochiti from all directions. J. R. McCowan of Albuquerque has just received an assay from a large sample of Cochiti ore which runs very high in gold and silver. Some ore leads are immense on the surface, and the mineral is quarried from the cuts in some instances forty feet wide.

Savannah days ago Mr. John Stocks, foreman of the blacksmith shop at the Empire mine, had an offer to go to Johannesburg, South Africa, to accept a similar position to the one which he now occupies, says the Grass Valley Telegraph. Mr. Stocks has been connected with the Empire, in his present capacity, for years, and he is considered one of the very best men in the business. It is not likely that Mr. Stocks will go, as Grass Valley is his home.

When the main shaft of the Bronze mine at Vanderbilt reached a point about 50 feet below the level last week, Foreman Sauerbrey noticed that the ore was of a different character and took a specimen to the surface, which, when assayed, showed a value of \$1118.83 per ton. The next day he took two samples, which he selected carefully in order that he might get only an average. These two samples, with the other, made an average of \$542.62 per ton in gold.

Goveanoa McConnell, of Idaho, is investigating the case of State Mining Inspector W. S. Hoskins, charged with gross neglect of duty in the recent Bunker Hill and Sullivan mine accident. In a letter to Governor McConnell, G. F. Whelan, secretary of the executive committee of the Miners' Union, says that the mine in question is a death trap and that this fact has been repeatedly brought to the notice of Inspector Hoskins, who paid no attention to the warning.

Winnsa A. Kaasar, a mining expert, has been arrested in this city on warrants charging him with obtaining \$1500 by false pretenses. The complainant is Dr. Ruth E. Newland, and the arrest is believed to be the outcome of a long-continued dispute over the ownership of the Jupiter gravel mine, near Angel's Camp, Calaveras county. Keefer was released on \$3000 bonds. He was extremely wroth over his arrest, and denounced the complainant in round terms, also accusing her of various unlawful actions in connection with the disposition of certain stock in the Jupiter mine to which she claimed ownership.

The annual report of the Osceola Copper Mining Company of Michigan shows that the cost of producing 6,715,870 pounds of refined copper at the mine in 1893 was 7.26 cents per pound, against 7.20 cents in 1892 and 7.63 in 1891. About 21 cents must be added to cover lay down cost in New York. The net income last year was \$102,448, and \$100,000 was given in dividends. The dividends for the previous two years were \$150,000 per annum. The Kearsage reports the cost of producing copper in 1893 at 9.32 cents, against 9 1/2 cents in 1892 and 8.84 cents in 1891. The Atlantic produced copper at 9.42 cents in 1893, against 11.90 in 1892.

A Practical Talk on Mining Geology.

By Taylor D. MacLeod.

"Knowledge is proud that he has learned so much;
Wisdom is humble that he knows no more."

There is a prevalent fault among mining men of limited experience in territory and practice, who claim that good mines can only exist under the local geological conditions they are personally familiar with.

Again, a man may be ever so good a metallurgist and have but a superficial knowledge of mining geology. His really meritorious ability in his special field may cause him to overlook the somewhat common-place fact that "the world do move"—that, in short, the point of the miners' pick has broken through the cap-rock of ancient lore and exposed the pay mineral of a wider knowledge.

The practical application of theoretical learning, supplemented by actual contact and practice in the field, makes the really competent mining geologist. This knowledge may have been acquired in the schools or may be self-taught, it matters not. Untold, they are a more perfect unity; divided, their adherents are apt to be stubbornly bigoted. The solely practical man ridicules "the fine-spun theories of the other side and gives ocular proof of the errors of the purely book savant. The theoretical scholar, serenely and with a half-suppressed smile of contempt, dismisses the arguments of his brother geologist of the pick with a few well-groomed phrases. Neither are right; both are wrong in a degree; the happy mean between these two. Extremes have been and are congenial, and the mutual interchange of experiments and discoveries of a mechanical, metallurgical or geological nature is producing that superior class of safe mining men peculiar to this western country.

Two Types of Mining Operators.—The older text books tell us we may not look for the precious metals in granite or limestone, and that they cannot exist in sandstone! I had thought these opinions were relegated to the dim and misty past, and had become as the "memory of a far-off dream," but I find them here, in this city of mining centers second to none in the land, a living factor governing somewhat the investment of capital in mining properties. A certain professor, eminent as a metallurgist, who has, it is said, a wide experience in mineral formations, advised an acquaintance of mine "to have nothing to do with mines of the noble metals that occur in a granite formation; that they were not and could not be persistent—go down—in depth!" This is certainly rough on the Anaconda and Granite mines of Montana, at the north, and the Congress gold mine of Arizona to the south, the latter with a record of \$10,000,000 produced. It was sold, a few days since, for \$1,250,000. Others could be cited *ad infinitum* as examples where the inclosing walls and country formation are of granite. Yet, despite the verdict of our learned brother, they will doubtless continue their regular dividends.

"There are more things in heaven and earth, Horatio,
Than are dreamt of in your philosophy."

Again, a certain literary miner, to the manor born, in my hearing voiced it as *his* experience "that a permanent gold ledge did not exist unless at least one of the walls was of slate, nor did he believe it could be found." Now this information—like the limber-jawed youth who so flippantly dispensed it—was quite refreshing. Wise in his generation, he confined the assertion to his personal experience, but should have stopped there.

A slate wall is a very desirable condition in a gold mine. none could be better; but if only those mines in a slate, or slate contact were producers of the yellow metal the bi-metallic problem would soon be solved, for there would not be nearly enough gold produced for the arts. The moneyed novice in mining affairs is generally a good single-banded listener, and such wild assertions as quoted above may result in harm.

Formations in Which Permanency May Be Expected.—Given a competent knowledge of terrestrial magnetism, in its bearings on minerals, the formations and fillings of veins, and, in short, the whole phenomena of geology in its relation to mining, it is impossible to form a correct opinion of any new and unexplored ground; and a reflective man will not advance an opinion on a territory or formation of which he knows nothing. Experience has shown that for permanent mining the older the rocks are, the better the prospect for deep and lasting works. It was the opinion of the late Sir William Logan that the gneiss of the Laurentian system was the oldest in the world, and every member of that ancient family refers us back to time so remote that time is too short a word to express our conception of duration. No *true vein* in those Laurentian granites, or their equivalents, the crystalline slates, will ever run out in depth. They may be profitably worked until water or some other unavoidable cause may make it too expensive.

Porphyry is an essential constituent, either as wall rock

or forming a dyke in connection with most, if not all, large bullion-producing mines. The great Comstock of Nevada was encased in a greenstone porphyry, called propylite, and it has been observed that when this porphyry runs out or ceases to exist, the mineral becomes low grade. Forty per cent of the value of these ores was in gold. At Nagybanja, in the mines of Transylvania, where large amounts of native gold and silver are produced, the rock is all porphyry. The richest mines in southern Siberia are in syenite and porphyry. The gold-bearing conglomerate reefs of Johannesburg, South Africa, are in quartzite. Limestone and quartzite contact walls, in a porphyry country rock, enclose the Vulture and Harqua Hala mines of Arizona. A brown sandstone is the matrix richly impregnated with silver at Silver Reef, Utah. Hence experience has finally taught us that the practical miner is correct in his statement that "silver is in veins and gold is where you find it."

How Little We Know.—And it comes to that, pray how much do any of us know, *practically* always, of the origin of metalliferous veins; and after separating each and every constituent element from an ore, knowing the percentage of each, who can return that rock with its minerals to its original condition? Sublimation, infiltration or any other *tion* is simply conjecture. Have our scientific experts read the riddle of that huge pipe vein, the Silver King of Arizona, or how came that peculiar and rich chimney of ore, the Bassic mine of Colorado, with its sheep-horns incrustated with silver chloride 70 feet down in the solid vein and numerous chunks and fragments of charred wood to the 300 level? True, we have many learned papers, by really scientific men, on the Bassic mine, but they don't agree, and I think we may sum it all up in the stanza by Pope:

Pretty in amber to observe the forms
Of hairs, or straws, or grubs, or worms!
The things we know are neither rich nor rare,
But wonder how the devil they got there.

When ore is out of the usual character, we simply experiment, and we have advanced but little in the absolute saving of the precious metals over the old Spanish or Mexican processes of a century ago. Great progress has been made in the mechanical department of ore manipulation, whereby we may handle tons where pounds were treated in days long since; but in actual metallurgy we have advanced but little. To the casual reader this may be rank heresy, but it is cold-blooded truth nevertheless.

Distinct from the average calling, there are no graduates in the school of mining, geology and metallurgy. Again, different from other lines of research, the vast possibilities and comparatively slow advance made does not discourage the student, but rather enthralls him with a glimpse of yet more to follow in the hoped-for near future.

For 62 years that eminently practical scientist, Prof. Melville Attwood, has wrestled with problems in applied metallurgy and the geology of mining. An enthusiastic student and clever resourceful experimenter, he said to the writer the other day: "Oh, my dear sir, the span of human life is too short and there is so much to learn."

A valuable paper on the origin of metalliferous veins by Prof. Attwood should be widely circulated and read by practical mining men when it is given out for publication. Let the reader compare the utterance of this veteran life student and active worker in the field of mining with the recitals of the average Jonah's gourd variety of mining expert, and the application of the lines introducing this letter is plain.

TAYLOR D. MACLEOD.

The Cripple Creek District.

A descriptive pamphlet of the Cripple Creek district, Colorado, just issued by J. W. Prouditt & Co., of Colorado Springs, will make interesting reading to all, especially to those whose attention has recently been particularly directed to the district by the mining troubles.

The district is near the base of Pike's Peak, 20 miles southwest from Colorado Springs, 44 miles from Pueblo and 70 miles from Denver. It consists of rolling hills, sparsely wooded, and small valleys and gulches. Gold has been known to exist there since 1859. No work of any importance in the way of prospecting the district was undertaken until 1861, though a tunnel in Aregna Creek was run in 1874, and in Poverty Gulch in 1879, both of which enterprises were unfruitful.

It was not until February, 1891, that any serious attempt was made to develop the district. Of course, some months passed before there were any tangible results. Several locations were taken up, and on some of these ore was found. As the facts came out, people were attracted thitherward, and by the end of 1892 there were estimated to be 2000 people on the ground. The output of gold in the district for 1892 was about \$600,000. Still greater progress marked the year 1893. Cripple Creek now has a population of 7000, a complete system of waterworks, an electric plant, two banks, ample hotels, and nearly all the conveniences of a town of that size—all practically the

outgrowth of two years. The bullion product of the district last year was \$2,463,500, an increase of \$1,800,500 over 1892. There is every reason to believe that the output will be larger this year. In 1892 there were 8½ miles of development—shafts and drifts—and in 1893 there were 7½ miles more added. There are 26 steam hoisting plants in operation against 5 at the end of 1892. Scores of locations have been made, but most of the bullion last year came out of half-a-dozen claims.

The metal output of Colorado for the past two years was as follows:

	1892.	1893.
Gold, ounces.....	267,538	401,307
Silver, ounces.....	26,542,135	25,304,750
Lead, tons.....	61,572	46,179
Copper, pounds.....	4,666,450	5,133,095

In 1892 silver was estimated at 86.8c per ounce, copper at 11c per pound, and lead at \$81 per ton. In 1893 silver was averaged at 77c, copper at 10c, and lead at \$72.30. Gold is figured at \$20.67 per ounce. Based on these figures, the metal product of Colorado for 1892 was \$34,059,229, and for 1893 \$31,621,742. According to these figures, the gold output of Colorado last year was \$8,295,016, against \$5,530,010 in 1892, most of the increase coming from the Cripple Creek region. W. F. Hendrick, an enthusiastic member of the Colorado Mining Stock Exchange, says: "The Little Johnny and Leadville mines at the new camp at Balfour are producing more gold than the great Treadwell mines. Over 50 wholly new gold mines have been established in 21 counties." These statements are certainly of an encouraging character, whatever may be the output at the end of the year.

Counting One Million.

They started in to count \$1,000,000 in worn silver coin at the Mint on Friday and will probably be at the task for a week or ten days, says the *Examiner* of March 25th. The money comes from the Sub-treasury, and the order for its transfer was made by the Treasurer at Washington.

The intention is to recoin it—an operation which will result in a loss of \$20,000 to the Government. The silver pieces had, however, become what is termed "uncurrent," and had accumulated at the Sub-treasury for a score of years until they had become a nuisance. They consist of halves, quarters, dimes and 5 and 3-cent pieces. Some of them would make the heart of the numismatist throb with envy. The idea of turning into the melting pot 50-cent coins going back nearly to the beginning of the century, 3 cent pieces which have not been struck since 1873, and twenties which were born in 1877, only to die within a couple of years, would drive him to despair.

The first consignment of \$100,000 of these coins was taken to the Mint yesterday morning in sacks of \$1000, whatever their denomination. They were then transferred to the south adjustment room, where 16 women were called in to count them, for in their abraded condition, weight would serve no criterion as to their value. Chief Clerk Robert Barnett looked out for the interests of the Mint and Cashier Thomas P. Burns watched over those of the Sub-treasury, of which he is general manager. The women were seated at three rows of stone-covered tables. Each was supplied with a wooden tray, a sack of \$1000 was dumped out between every two of them, and the counting began.

They did not find it agreeable work. They have been accustomed to handle clean, new coin from the dies. That which they had to handle yesterday was worn and dirty. Not only that, but the piles of coin would not equalize, except approximately, and great care had to be exercised in counting it. About two-thirds of the coin consists of halves, the remainder being made up of pieces of smaller denominations. The three-cent pieces were first taken up. There was only five dollars' worth of them. Then came the turn of forty dollars' worth of 20-cent pieces. Halves and quarters followed, alternatively, as handling one set of money for a long period becomes very painful to the counter.

Yesterday's work commenced at 10:45 o'clock and continued until 4 o'clock in the afternoon. Hereafter, however, the counting will be carried on from 9 A. M. until noon and from 1 to 4 P. M. until the task is finished.

A DOZEN MINERS have just sailed for Cook's inlet, Alaska, on the schooner Melancthon. Reports from Alaska are that wherever black sand is found in the neighborhood of Cook's inlet gold is obtainable. The source of this fine gold has been traced to the placers on the streams 40 or 50 miles from the inlet. One station lies 830 miles above Sitka; it is off the steamer route and distant from the lines of travel to the Yukon gold fields. Its isolation is the reason that so little has been known about the gold-bearing sands and placers of that portion of Alaska. One trouble with which the prospector has to contend is that there is no surface showing of mineral, no outcropping visible, as in California and the Rocky Mountain States and Territories. The whole country is covered with a heavy growth of moss, which has to be raked off before the prospector can begin work on the gravel which lies beneath.

Silver-Lead Smelting Practice.

In Two Parts—Part I.

Walter Renton Ingalls in *Engineering Magazine*.

One of the most important factors in the great increase in the production of silver in the United States during the past ten years has been the improvement in the silver-lead smelting works and their processes, which, together with the extension of railways through the Rocky mountains, has made it possible to treat ores that formerly could not be mined at a profit. The advance made in this direction has been so far-reaching in its results that the methods of silver milling, like amalgamation and lixiviation, which belong distinctively to the metallurgy of silver, have fallen off notably in relative importance, and now more than half the silver turned out in the United States comes from argentiferous lead ores and those smelted with them. On the other hand, the lead industry has become more interwoven with silver mining, until, out of the 620,000 metric tons of the baser metal that were produced in the world in 1892, much more than half was derived from silver-bearing ores. In the United States alone the percentage was higher, only about 20 per cent of the whole product coming from the producers of soft lead in the Mississippi valley.

The silver-lead smelting industry in the United States is of comparatively recent origin, the first successful works having been erected in 1867 at Argenta, Mont., where argentiferous galena ores were reduced in small blast furnaces, each furnace treating from two to five tons of ore per day. Two years later the great silver-lead deposits of Enreka, Nev., were opened and furnaces were erected at that place. In 1870, works were established at Salt Lake City, Utah, to treat the ores mined in Bingham and Cottonwood canyons. From these beginnings the American practice of silver-lead smelting has been developed.

The second stage of the industry dates back to the opening of the great bodies of lead carbonate ore at Leadville, Colo., in 1878, which was followed immediately by the erection of smelting works at that place, where in 1880 there were 13 plants in operation (three more being out of blast), which produced 36,000 tons of lead, or nearly 35 per cent of all that was turned out in the United States in that year. The Leadville works of this time were much superior to those of Eureka and Salt Lake City of ten years previous, a better type of furnace having been introduced and the methods of smelting having been improved; but both the cost of smelting and the losses in metal were still high, and the defects of these works in comparison with the model plants of the present day would be apparent even to the layman.

A noteworthy feature of the silver-lead smelting industry of the United States during the first 15 years of its history was the multiplication of small plants in the immediate vicinity of important mines. Few of these remained long in operation, owing to exhaustion of the mines near which they were located or inability to meet the competition of the larger and more economical plants that were built subsequently, and the policy of erecting works at isolated points, or for treating ores of individual mines, is now recognized to be unwise. The ruins of such works that are to be found scattered through the Rocky mountains are monuments to one of the steps in advance in the practice of lead smelting in the United States.

About ten years ago lead-smelting works were established at Denver and Pueblo, in Colorado, at the foot of the Front Range of the Rocky mountains, and with the growth of these began the third and final period in the development of the industry in the United States. These works were so located that they could command the ores from many districts through the branches of the railway systems at whose centers they were built, and they were thus able to obtain better and more profitable mixtures for smelting than the isolated works in the mountains, which were dependent upon single groups of mines. They had the advantages, moreover, of cheaper labor, cheaper fuel and fluxes, cheaper supplies and cheap freights on ore from the railways, which were interested naturally in concentrating the industry at points giving them the most carriage. The smaller and less favorably situated custom works could not stand the competition with the new valley smelters, and one by one were forced to close down, with the exception of a few of the Leadville works, those at Salt Lake City, which occupy a more or less central position, and a few others.

The refiners of silver-lead bullion, established chiefly at Omaha, Argentine (Kansas), St. Louis, Chicago, Mansfield (near Pittsburg), Newark and San Francisco, also have smelting departments, and some of them, especially the three first mentioned, handle considerable quantities of crude ore. There is a close connection between most of the smelting and refining companies, and the base bullion produced by the former is turned over to the corresponding refining works; so the en-

tire treatment from smelting the crude ore to marketing the refined products is done practically by the same concern. Thus all the bullion of the Colorado Smelting Company, of Pueblo, and the Montana Smelting Company, of Great Falls, goes to the National Smelting and Refining Company, of Chicago; that of the American Mining and Smelting Company, of Leadville, goes to the Chicago and Ancona Smelting and Refining Company, of Illinois, and that of the Mingo Smelting Company, of Salt Lake City, goes to the Pennsylvania Lead Company, at Mansfield. The great Arkansas Valley Works at Leadville and the works at El Paso, Texas, are owned by the Consolidated Kansas City Smelting and Refining Company, which refines all its bullion at Argentine. The Omaha and Grant Smelting and Refining Company and the Pueblo Smelting and Refining Company refine their own bullion at Omaha and Pueblo, respectively, and the Globe Smelting Company has recently established a department at its works in Denver for the same purpose. This affiliation between smelting and refining companies, and the erection of refining works (formerly grouped on the Atlantic coast, with the exception of one on the Pacific) further west, and at the smelting works themselves, has been one of the important tendencies of recent years, being the natural sequence of the concentration of the smelting works. All of the refining companies buy also bullion from outside works, including those of the Republic of Mexico, about 13,000 tons of bullion from the latter having been desilverized in the United States in 1892.

In theory the smelting of argentiferous lead ores is extremely simple, but like most metallurgical processes it is more intricate in practice, wherein extraneous complications enter. There are various methods of smelting, but in the United States only one—roasting and reduction—is in common use. The lead in the ore has first to be oxidized by roasting, if present originally in the form of sulphide (galena), but, if already oxidized (as in the case of the Leadville carbonates), of course no preliminary treatment is necessary. It is then charged into a shaft-furnace together with a certain proportion of limestone, oxide of iron, and fuel, which may be charcoal or coke or a mixture of both. The iron and limestone are added to the ore for the purpose of making a fusible slag. Descending in the furnace the carbonic acid is first driven from the limestone and ore; at a lower zone the charge fuses, the iron and lime combining with the silica of the ore to form a double silicate of iron and lime, while the oxide of lead is reduced by the carbon of the fuel, with the formation of carbonic-acid gas and metallic lead, which collects the gold and silver from the ore and trickles down into the bottom of the furnace, which is called the crucible. The molten slag, being much lighter than the lead, floats on top of it, and is separated by tapping from the furnace at a higher level, the method varying in detail in different types of furnaces.

This is the general principle of the roast-reduction process of lead smelting, but in practice there are important modifications. Thus part of the lead ore is sometimes fused on a reverberatory hearth previous to smelting in the blast furnace, whereby the lead is converted into silicate, in which form it is charged instead of oxide. Furthermore, it is not economical to oxidize all the sulphide ore, galena, and pyrite, and the furnace charge always contains sulphur. Then there are other metals in the ores, such as copper, arsenic, and zinc, and earthy materials, such as magnesia, baryta, and alumina, which have to be disposed of, and the proportions of iron, lime, and silica in the smelting mixture have to be adjusted so as to effect this. The sulphide and silicate of lead are decomposed by iron with the precipitation metallic lead. The bisulphides of iron and copper are reduced by iron to monosulphides, forming a matte, so called. The arsenic also combines with iron as arsenide of iron or speiss. The matte and speiss, both of which carry gold and silver, are heavier than the slag and lighter than the bullion, sinking consequently to a level in the crucible between the two. They are usually drawn off with the slag, however, and separated from it outside of the furnace, after which they are subjected to further treatment (roasting and resmelting) for the recovery of their metallic contents. The earthy oxides, like alumina, baryta, and magnesia, which commonly occur in lead ores, are taken up into the slag as silicates. Zinc, which is the foreign element most dreaded by the lead-smelter, is disposed of in part in the same manner, but in part it is driven off by volatilization. In whatever way it is gotten rid of, however, it leads to increased cost in smelting, wherefore it is customary to make a higher charge for smelting zinc-bearing ores according to the excess in zinc over a certain limit, which may be, for instance, 7 per cent.

The method of calculating furnace charges, which is the duty of the metallurgist or superintendent of the works, is too complicated to be explained here in detail, but its principle, which is simple, may be indicated. The smelter buys ores from many mines in lots varying from a few

hundred pounds to 100 tons or more, low grade ore being shipped usually in larger lots than high grade ore. On receipt at the smelting works the ore is sampled and assayed for gold, silver, and lead, and the settlement with the miner is made on these results. The sample is also analyzed to determine its contents in iron, alumina, manganese, zinc, sulphur, silica, and other elements; in the case of sulphide ores a sample is taken after roasting and analyzed in the same manner.

Analyses are made also of iron, flux, limestone and fuel. Having arrived at the composition of his material, the metallurgist calculates the proportion of each required to make the proper mixture for the furnace charge. There must be sufficient iron and lime to combine with the silica of the ore in making a slag of desired composition. The ore itself will contain some iron, and perhaps some lime. What more may be needed must be obtained by adding iron, flux and limestone. Iron must also be allowed for combination with the sulphur and arsenic in the ore. Lead is non-fusible, but plays an all-important part in the furnace as the collecting agent for the precious metals, for which purpose it must be present in certain proportion; hence the ores used in making the mixture must be selected so as to give the charge the proper amount of lead. The silver and gold contents of the ore must be considered also, in order to make bullion of an economical grade. The composition of the charge having been determined, the proper proportion of each kind of ore is wheeled to a great bin, where it is made up into a bed, amounting to a thousand tons or more, which is drawn upon for the furnaces as needed, the proportion of limestone and fuel being weighed out and mixed with the charge on feeding.

American Improvements and Inventions.

Discussion by T. A. Rickard of Denver, Colo., of Paper Read by James Douglas, New York, before the American Engineering Congress.

Mr. Douglas's paper will be of great value for future reference; but the ground which it covers is so extensive that it was impossible not to make some omissions and some small errors.

The description of the two types of stamp mills (those of Colorado and those of California) is open to criticism. The California "stamp-head and stem" are said to weigh from 700 to 800 pounds. This is not accurate; the total weight varies from 750 to 1000 pounds. The most usual weight at the present time is 850 pounds, and it is distributed as follows: Stem, 335 pounds; stamp-head, 225 pounds; shoe, 160 pounds.

The pulp is said to be discharged from "both sides." Does the author mean the back and the front of the mortar? Double-discharge mortars have long been abandoned in the gold-mining regions of California and Colorado, though they are still retained in silver mills.

The Colorado stamp weighs 500 to 600 pounds. Stamps weighing so little as 400 pounds are not now used. A 550-pound stamp would have its weight distributed as follows: Stem, 220 pounds; head, 185 pounds; tappet, 60 pounds; and shoe, 85 pounds.

The typical Colorado (Gilpin county) mill is not characterized by so rapid a drop as 40 per minute. The minimum is 26 to 28; the maximum, 30 to 32.

In the matter of concentrating machines of the vanner class, Mr. Douglas mentions those most commonly in use. He very properly does not express any preference for any one type, yet I feel that there is one fact to which attention may be called. The experience of the millmen of the chief gold-milling centers of California (Amador and Nevada counties) gives unanimous testimony to the effect that the Frue vanner requires less attention and gives less trouble than any of the other machines which have been constructed upon the principle of the endless rubber belt.

In the matter of concentration after amalgamation in an ordinary gold stamp mill, the American metallurgist has no great reason to feel proud. There has been a marked tendency to adopt a follow-my-leader policy. That two Frue vanners should treat the pulp discharged by five stamps is a rule slavishly followed, whether those stamps crush 8 or 15 tons per day, and whether the ore crushed contains 0.5 or 5 per cent of the material concentrated.

I would also draw attention to a mistake which others have doubtless remarked long ago. The passage of all the pulp direct to the vanner is surely wrong in principle. Some effort at sizing should precede concentration. Such sizing does not seem a costly or difficult operation. As it is now, the vanner is called upon to concentrate particles of pulp ranging from 30-mesh to impalpable slime.

The designing and building of a mill is left too much in the hands of the foundry and too little to the man who is to use it. Again, the manager usually gives more attention to the winning of the ore than to the subsequent extraction of the values in it. There is room for much improvement in these directions.

In referring to the system of hydraulicking used in the

California gravel mines, Mr. Douglas has omitted any reference to the "elevator." This machine is a truly American invention, and has added largely to the areas available for hydraulic mining.

The Caribou Mines

John Bowren, gold commissioner of the Caribou district in British Columbia, is a guest at the Lick, says the *Call*. Mr. Bowren went to British Columbia 32 years ago, making the trip overland from Winnipeg through the Canadian Northwest by ox team. For the past 20 years he has held the position of gold commissioner.

"The annual output from the Caribou district is about \$200,000," said Mr. Bowren. "Quite an influx of miners from California and Colorado is now taking place, and we look to see a great development. American miners are cordially welcome, as their experience makes them invaluable to the district. The way of reaching there from Vancouver is to take the Canadian Pacific to Ashcroft, where a weekly stage connects with the mines about 200 miles distant. When the British Pacific is constructed, which will run from Victoria, on Vancouver's Island, some distance to the north and cross to the mainland where the waters narrow, thence proceeding in an easterly direction, we shall have rail communication with the rest of the world.

"The gold is found in placers and mined largely by the hydraulic process. Miners, even with the old-fashioned rockers, make from \$2.50 a day upward. Much English and American capital is going into the district. Miners in the employ of companies are paid \$4 a day. There are about 2000 miners in the district, many of whom are old Californians who went to the Fraser river excitement in 1858.

"Formerly the method of mining was to sink shafts from 25 to 100 feet and then make drives along the bedrock. Now leases are being made on the streams, and the system of dredging employed in New Zealand is being introduced. The dredging is performed by suction, and can be made to pay, it is thought, at five cents in gold to the yard. The dredges can work in 25 feet of water, bringing up the gravel in much the same way that the ooze and mud is brought up in dredging for the improvement of harbors.

"J. S. Hawks has a lease of ten miles along the Smoky river. The lease runs for 20 years. He is now in this city arranging for dredging machinery.

"The mining laws of Canada are very liberal," continued Mr. Bowren. "A license costs \$5, the recording of a claim \$2.50, and the provincial revenue tax, imposed on all miners, is \$3 in a lifetime. These are all the imposts. Foreigners have the same privileges as British subjects."

Good Luck for Pocket Miners.

The pocket miners in the vicinity of Sonora are enjoying a season of prosperity. Pocket mining is one of the most exciting of all industries. In one pan a color cannot be seen, and the next may reveal to the gaze of the prospector bright, glittering gold, in one bunch sometimes reaching into the thousands, while again a prospect may be followed for months without success. Many large deposits have been passed, in trying to make too much ground, by the miner, and years after found by those who were lucky and experienced in the art. Prospectors have run within a few feet of a fortune and abandoned their claim for those more fortunate to extract what the former owners would have found had they not been disheartened.

The Tuolumne Independent reports that about four weeks ago Mike Terzich, while prospecting in an old abandoned shaft which was about ten feet in depth, on Bald Mountain near the famous Sell mine, found a good prospect. He sank about two feet when he took out a deposit of about \$60.

Not being able to work the claim alone to advantage, he took in two partners, Yonco Terzich and Wm. Punter. They at once started a tunnel about twenty feet below the shaft, to strike the pay shoot, and had worked about three weeks, when their labors were rewarded March 5th by finding a pocket of between two and three thousand dollars about two feet from where the first bunch was secured. This shaft was formerly worked by George Topping, and that young man is now wondering why he did not sink a few feet farther. Prospectors have been on the hill and located claims to the north and south, so that now not even a foot can be taken up.

J. D. Sellick and son, working a claim on Wolfing's hill, took out a pocket recently of about \$1,400.

Gene Elshree extracted \$1,500 from the Stewart claim, near Brown's Flat, a short time since.

Joe Joseph and Ed Sincok are reported to have taken ten pounds of gold from their mine near Brown's Flat in one day recently.

The Chenoweth brothers recently unearthed a pocket of nearly \$2,000.

Temperatures in Deep Mines.

M. Joseph Libert, Chief Engineer, Corps of Mines, Belgium, in a recent communication on Temperature and Nature of Waters in Deep Collieries, made to the Belgian Geological Society, gives some interesting data on the increase of temperature due to increased depths at the Produits colliery, Mons. The mouth of the shaft where the observations were taken was 246 feet above the level of the sea. The lowest workings in coal were at a depth of 2132 feet, and the total depth of the opening was 3773 feet.

The temperature of the rocks was measured by a specially constructed mercurial thermometer, enclosed in a shot hole with a clay plug, the thermometer being kept in this position for two hours. The thermometer was about a meter (3.281 feet) long. The reservoir was protected by a perforated iron plate, fitted to the hollow cylinder of wood in which the tube was enclosed, and the latter with the reservoir was inserted in the shot hole for a length of two feet. In the portion projecting beyond the hole, the cylinder was cut out so as to permit the reading of the mercurial column.

On February 6, 1889, at the foot of the shaft, at a depth of 3363 feet, the thermometer placed in a shot hole three feet long showed a temperature of 107½° Fahrenheit, while that of the air at the foot of the shaft was 82° Fahr.

More complete observations made later showed the following results:

October 16, 1889.	
Temperature on the surface.....	43° Fahr.
Temperature at a depth of 3117 feet.....	68 Fahr.
Temperature at a depth of 3773 feet.....	87 Fahr.
Temperature at a depth of 3773 feet.....	116½ Fahr.
December 21, 1889.	
Temperature on the surface.....	25° Fahr.
Temperature at a depth of 3117 feet.....	68 Fahr.
Temperature at a depth of 3773 feet.....	86 Fahr.
Temperature at a depth of 3773 feet.....	104 Fahr.
December 31, 1890.	
Temperature on the surface.....	17½° Fahr.
Temperature at a depth of 3117 feet.....	50 Fahr.
Temperature at a depth of 3773 feet.....	86 Fahr.
Temperature at a depth of 3773 feet.....	104 Fahr.

At a depth of 3773 feet an exploring drift was driven toward the north a distance of 235 yards. A borehole preceding the advance of the drift tapped a spring of water, the temperature of which was 118° Fahr. This water came from fissures in a bed of sandstone belonging to the north slope of the basin, and in a completely virgin region. It is reasonable to suppose that the temperature of this water is the same as that of the rocks occurring at that depth, and it agrees very well with that found on Oct. 16, 1889, in the shot hole at the bottom of the shaft. Subsequent experiments, however, proved an appreciable diminution of temperature, which must have been chiefly due to the cooling of the rocks in the neighborhood of the excavations by the ventilating current, which was necessarily very strong in order to make it possible for the men to remain there.

It may be admitted that, beyond the depth of 82 feet, variations of temperature in the atmosphere exert no influence, and that at this depth of 82 feet the temperature is equal to the annual mean of the air on the surface at the point under consideration. Thus, if we assume the mean annual temperature to be 50° Fahr. In the present instance, we deduce the mean geothermic degree of

$$\frac{3773-82}{118-50} = 54 \text{ ft.}$$

This result agrees almost exactly with the general mean obtained by Cornet in the various experiments which he made in the collieries of the Conchard de Mons. The rate of increase in depth for a degree Fahrenheit was 45 feet. In Cornet's experiments the depth was only 1670 feet, and they were made in unventilated headings at a considerable distance from the shaft, so that it may be presumed that there would not be so close an agreement in similar conditions of depth. Prof. J. Prestwich, whose paper on "Underground Temperatures" was published in the proceedings of the Royal Society of London, in 1886, found, from a comparison of the results of various experiments made in English and Belgian collieries, a mean rate of increase of 1° Fahr. for each 49.5 feet in depth.

In the opinion of M. Libert, the increase of temperature in rocks does not appear so simple as to be represented by an arithmetical progression, and therefore the experiments made at the Produits colliery do not furnish in themselves sufficiently exact data on which to base a rate of progression. However, if the results obtained at this colliery are combined with an observation made in the No. 1 shaft of the Grand Buisson colliery, in the same basin, and the mouth of which is 292.3 feet above the level of the sea, it is possible to obtain information with a certain degree of value. At the last-named shaft, at a depth of 2264 feet, a strong feeder of water with a temperature of 80½° Fahr. was struck. By comparing this temperature with that of the spring struck in the exploring drift in the Produits shaft

it will be found that the increase of temperature of 1° Fahr. takes place for every 41.2 feet of depth.

This divergence is so great that even the error of one or two degrees in the adjustment of either one of the two thermometers will not account for it. According as either one or the other of these figures is adopted, it may be deduced that between the surface and a depth of 2215 feet the increase of temperature will be 1° Fahr. for every 69.3 feet or 65.6 feet. In support of this view, M. Libert quotes the results obtained by M. Walferdin in the borehole at Le Creusot, as noted in the *Compte-Rendus* of the Paris Academy of Science. He found that the heat of the earth increases from the surface to a depth of 1800 feet at the rate of 1° Fahr. for every 56 feet, and that between 1800 feet and 2625 feet the increase is 1° Fahr. for every 43.4 feet.

Bauxite Mining in Alabama.

The growing importance of aluminum gives interest to the ore from which it is obtained. This ore derives its name bauxite, or banxite as it is more commonly called, from the town of Beaux, or Baux, near Arles, in southern France, where it has been found in large quantities.

An article by Henry McCalley, in *Science*, is our authority for the following statements concerning the present status of the mining of the ore in the South:

Of the four companies which have been engaged in the industry, only two are now operating. They are known as the Republic Mining and Manufacturing Company and the Southern Bauxite Mining and Manufacturing Company.

But three mines are being worked at present; they are all near Rock Ruo, Alabama. An average sample of the ore from one of these mines shows on analysis about this composition:

Alumina.....	61.00
Ferric oxide.....	2.25
Silica.....	2.10
Titanic acid.....	3.12
Water.....	31.58

Samples from the other mines differ a little from this; they yield from three to five per cent less of alumina. The mining is easy, as the ore is soft and can generally be taken out with a pick; it is, however, rather expensive, as the ore varies so much in quality that it must be carefully sorted by hand and with the screen.

The diggings are on side hills, and are drained by open ditches. The ore whose analysis has been given is about 35 feet thick in the mine. It is concretionary; the best of it is found in a middle seam four or five feet thick.

Owing to its hygroscopic property all the ore has to be dried before it is shipped.

This is done by spreading it out in the open air, for the action of the sun and wind.

When favorable tariff legislation makes it safe to increase the working capacity of these mines, artificial means of drying and better drainage facilities will be adopted.

At present only the best grade of ore is shipped. It is used for the manufacture of alum, which could as well be made from the inferior ore now lying in heaps about the mines, but to compete with the cheap imported ores, set over by men who had the entire business in their hands before these mines were open, only the best product can be put upon the market.

THERE were 96,996 shares represented at the Chollar Mining Company's meeting on March 21st out of a total of 112,000 shares, in which the mine is divided. The old Board was re-elected, as follows: A. K. P. Harmon (president), Thomas Cole, Thomas Anderson, E. P. Barrett and D. C. Bates. Charles E. Elliott was continued as secretary and H. M. Gorham as superintendent. The report of the latter showed 1588 tons ore reduced during the year, yielding \$25,174 gross, on which was realized \$16,602 in gold coin, the difference representing the discount on silver. The secretary reported an overdraft of \$11,983. To meet this deficit, and to provide funds for future operations, the directors immediately levied an assessment of 20 cents per share. This will realize \$22,400. The previous assessment of 10 cents per share became delinquent in January.

THE United States Minister at Santiago has informed the Department of State that the Government of Chile will sell at public auction at that city June 15th eight of the most valuable and extensive of the nitrate concessions and a large area of nitrate deposits that have never been touched. Bonds and securities amounting to 40 per cent of the valuation of the property must be deposited by the bidders and 20 per cent of the purchase money must be paid into the treasury, with ten deferred payments to be secured by mortgage. Colonel North, the nitrate king, now has most of the concessions that are to be sold, but instead of renewing them directly the Government expects to get better terms by open competition at auction. The English Government opposes the sale.

Nickel Mining in New Caledonia.

Nickel mining in New Caledonia was the subject of a paper read recently at the London Institution of Mining Engineers. Mr. Garland traced the discovery of nickel ore in New Caledonia to M. Jules Garnier, who, when engaged in a geological survey of the island in 1864, met with a strange green mineral, which was destined some years later to become one of the most important sources of nickel in the world. At first there was a good deal of misconception as to the true nature of the mineral, and for a time its green color gave rise to the belief that it was an ore of copper; and, indeed, a shipment was, it is said, made to a smelting works in Sydney to determine its value for copper. It is needless to say that the attempt to extract copper from the ore proved futile. It is not, however, the first time that an ore of nickel has been mistaken for copper ore, for it is well known that *Kupfernickel* was so called by the German miners because they frequently mistook it for an ore of copper. It is recorded that when the French colonists realized the importance of the discovery, the government offices were daily besieged by applicants for concessions, and that the excitement became intense. The deposits at Mont d'Or were found to be unremunerative, but it was not long before fresh discoveries were made in other parts of the southern half of the country along the east coast, and mining for nickel soon became an established industry. For the first few years the mines were worked solely by private enterprise, but in 1881 fresh impetus was given to the new industry by the starting of a big French company, "La Societe le Nickel," locally known as the "Nickel Co.," which, though not the only nickel mining company in the island, is far and away the most important. It has acquired mining rights over an immense area; it works a large number of mines under the direction of its own officers, and leases a large number of others; it is the purchaser of all the nickel ore raised in the island; it has a monopoly of the shipment of the ore to Europe, and it has, moreover, enormous influence in the country. Mr. Garland found, during his recent visit, that the eagerness to acquire nickel concessions, though not so keen as it is reported to have been formerly, has by no means died out, and that new grants are constantly being demanded from, and granted by, the Mining Department at Noumea. The production has now reached over 60,000 tons of nickel ore per annum, is still increasing, and it would appear that nickel mining in this far-off French colony (and penal settlement) was still in its infancy. From official statistics published at Noumea, and brought down to July 1, 1892, he gathered that the total number of mines at that date was 324 (of which about 80 were in active operation), comprising an area of 48,956 hectares, or, say, 120,921 acres.

The paper, after dealing with the geological and mineralogical aspects of the question, went on to say that the mode of working is either by tunnel mining or by open quarrying. The first-named method is adopted when the veins happen to be fairly persistent and of good width; the latter method when they are small—say less than 6 ins. to 12 ins.—and when stockworks occur. It sometimes happens that both systems come into operation in different parts of the same deposit. For example, the larger veins are exploited by tunnels and subsequently the cap or top of the peak is quarried for the sake of the numerous small veins. When underground mining is resorted to, the system followed is that universally practiced in metal mining, and familiar to all mining men. A series of tunnels or adit levels, one below another, is extended into the mountain along the vein, and connected in the usual way by winzes and rises for ventilation, and for convenience of stopping. Mention was made of another nickel mine visited by the author, where the bulk of the ore was raised by open quarrying, but where there was also some underground mining of a somewhat irregular kind. The veins, some of them several inches in thickness, were not persistent in any one direction, and thus it happened that after driving on a vein a few yards it might be cut off by a productive cross vein; the latter would then be followed right and left till another interruption occurred or the vein became poor. A winze would then be sunk or a rise put up to prove the vein, and, perhaps, fresh levels driven in different directions from the bottom of the one or the top of the other; and thus the mine, to a visitor, seems to be a perfect labyrinth. Quarrying is done in terraces from the top downward, each terrace having a wide floor on which the rock is blasted down, and where the ore is prepared for market. The preparation of the ore for the market is of the simplest description. The crude ore having been reduced by spalling to suitable size, a portion, consisting of mixed ore and rock, is separated by cobbing, the cobbled ore being always of high grade. The remaining portion, consisting of the fine ore a good deal mixed with stone, is all carefully collected and screened in hand

sieves of $\frac{1}{2}$ -in. or $\frac{3}{4}$ -in. holes. The fine ore which passes through is not further treated; the coarse ore which remains in the sieve is hand-picked, the useless stone being removed. The picked ore is now thrown with the fines and the cobblings, and the whole mixed together forms the marketable product. As might be expected, the ore prepared in this crude way, by screening and hand separation without the aid of water, contains a large proportion of stone and dirt; but this is the system universally adopted throughout the nickel-mining district, the difference in the specific gravity between the nickel ore and the country rock not being sufficient to make easy and economical separation by water practicable.

The scarcity of labor is one of the chief difficulties in connection with mining in New Caledonia, and Kanakas are imported from the neighboring islands, and even Chinese and Japanese are sometimes imported in considerable numbers. It is a novel and interesting experience to see a big mine or a series of quarries in full work, manned entirely by convicts, guarded by a number of warders all armed with revolvers. Some of the men are drilling holes, others blasting with dynamite, some spalling, cobbing, screening, or hand picking, while others are tramming or wheeling away the waste rock. Some also are placing the ore in bags ready for transport down the mountain side, on cable ladders or tramways, to the wharf for shipment. All is activity, but there is an absence of zest and cheerfulness in the performance of the task, for, naturally enough, the convict is not notorious for the energy and enthusiasm he throws into his work. At a group of four mines at Thio, owned by the Nickel Co., which the writer was courteously allowed to visit, 900 men were employed, 750 of whom were convicts, and 150 *libere*. The latter are not employed at the same mines as the former.

Mr. Garland closed his paper by mentioning that the nickel deposits of New Caledonia are said to extend only to a limited depth, one formerly important mine having, it is reported, ceased to yield nickel at a depth of 300 ft., the ore at that depth passing into the white silicate of magnesia. He has no evidence which would justify him in venturing a decided opinion on this point, but the enormous area which the nickeliferous serpentines cover seem to indicate that it will be a very long period before the nickel deposits of New Caledonia will become exhausted.

Petroleum Industry of Galicia.

Although the petroleum wells of the United States and of Russia do not seem by any means to be exhausted, it is of the highest importance to discover what other countries are prepared in their turn to supply mineral oil, says the *American Manufacturer*. As can easily be understood, this liquid combustible is constantly being adapted to more and more numerous, and to more and more varied employments. It is no longer restricted to lighting purposes. Special motor engines consume enormous quantities of it day after day. It would, therefore, be as well to devote some attention to the petroleum basin of Austria, the more so as it has hitherto almost entirely escaped notice.

Of all the provinces of Austria, Galicia is the one which is best provided with subterranean wealth. The mineral riches of this part of the Empire are very varied and exceedingly abundant; they include iron, zinc, lead, and even auriferous sand. Salt beds, the product of which is enormous, form an immense semi-circle through the whole length of the country; they begin near Cracow, with the celebrated mines of Wieliczka, and they extend to the Bukovine river.

But, as is often the case, it is precisely in the neighborhood of these salt beds that petroleum is found. If we glance at the map of Austria, we see that the Carpathians, between upper Silesia and Wallachia, describe a vast curve, the concavity of which is toward the northeast. This chain of mountains forms the frontier of Galicia, and it is upon its concave side that the petroleum rocks are found in a zone parallel to that of the salt works. The petroleum basin is formed of a multitude of little beds, most of them about 3 km. in breadth and 300 in length.

The existence of petroleum in this country has long been recognized, but no means have been taken to determine its exact nature. In old days the Galician peasants were accustomed to extract from the local soil a bituminous substance, which they used to oil their carts. There is, indeed, a tradition that it was at Cracow that the first petroleum lamp was ever used. According to M. Steinman, it was about 1830 that the Galicians began to work a substance called *ropa*, which is simply the raw oil, out of which they manufactured asphalt and a lamp oil. A chemist of Lemberg was the first to carry out this trade on any scale. This was the time when the "oil fever" was breaking out in America; the rumor of fortunes so rapidly made in the United States found its way to Galicia, and it was felt then that such a source of wealth ought no longer to be neglected.

Mechanical Arrangements in Underground Operations.

Mr. R. H. Wynne, in a paper on this subject read before the North Staffordshire Mining Institute, ably compared the relative value and efficiency of the various mechanical arrangements used in mines. In commenting on mine haulage he called attention to the fact that, inasmuch as large outputs and consequently large working areas were essential in the profitable working of collieries, the necessity arose for the most approved system of underground haulage, the cost of which is one of the most important items in the production of the coal. He stated that the using of horses or mules for the underground conveyance of coal except for short distances during the opening out of a colliery, and bringing the wagons from the face to the hauling stations, must be replaced by some more economical means of locomotion. Having discussed the advantages and the disadvantages of the use of steam underground, he referred to compressed air. He said unquestionably compressed air was a convenient form in which to transmit power from the surface for use underground for a variety of purposes—for example, hauling, pumping, heading by machine, drilling holes for blasting, and to drive coal-cutting machines; and with its convenience might be combined safety in using, freedom from damage to roads by heat or leakage, referred to in relation to steam. He referred to its use in different mines, and gave opinions of various writers as to its value. As compared with steam he thought compressed air was much better adapted for transmitting power considerable distances underground, but this had its limits, looking at the increase in the size of pipes to carry the air extremely long distances, and the extra power necessary to be applied to the compressor to attain the required pressure. Moreover, the exhaust from the motors had the effect of cooling the air current, and adding a little to its volume; whereas steam had the opposite effect on the temperature, and required special means to be adopted for its disposal.

Electricity as a medium for the transmission of power had not by any means attained its fullest development, but during the past four or five years its use for colliery purposes had received an immense impetus, and there was no doubt it would become in a short time the medium *par excellence* for the transmission of power over long distances underground for a variety of purposes—for example, hauling at far-away stations where the main haulage worked from the surface or engine at the bottom of the shaft was not conveniently applicable; pumping water from the bottom of inclines under similar circumstances; and actuating drilling and coal-cutting machines. It also afforded the means of obtaining superior lighting on the surface and in the main roads underground, and most likely in the near future a portable and safe light for the working collier.

The advantages of an electric system for districts not easily accessible to direct steam power or compressed air motor might be summarized thus: "A reduction of capital expenditure when compared with other systems. Facility in putting conducting cables down shafts and laying them underground to distant motors. Small loss from resistance in cable or leakage of current to the earth when compared with waste in a compressed air system. Lowness of cost of maintenance. Speed with which an electric plant can be erected and set to work." Sparking at the motor, from which some danger might be apprehended in a fiery mine, was said to have been overcome by the adoption of the enclosed motor. The breakage of a cable and the sparking therefrom was a contingency to be considered. Although the advantages of electricity were considerable, it was doubtful whether it would be good policy to adopt such a system where steam could be used direct from the surface for haulage purposes; but there did not appear to be the least doubt of the value of electric motors in situations not suitable for other mechanical power.

Speaking upon other points relating to underground haulage, Mr. Wynne proceeded to say there were the endless rope, the main and tail rope, and the simple tail rope. The endless rope, with the slow movement and steady flow of traffic, appeared to be in greater favor than other systems. It was probable that in his district, with its great variety of inclination of the seams, nature of the roof and floor, and other circumstances, difficulties were present which did not occur to those engaged in more favored districts, calling for greater caution and consideration before being committed to a large outlay on any particular system. It was a question for consideration whether in the case of a seam dipping at a considerable angle, and supposing that an endless rope would be advantageous on the local ways, it would be judicious and economical to construct the dip roads at such an angle to the full dip of the seam as to render the endless rope system available throughout.

Scientific Progress.

Prof. Davidson in the East.

Prof. George Davidson, of the United States Coast and Geodetic Survey, returned home recently after an absence from this city of nearly three months, and his observations are thus noted in the *Examiner*: Prof. Davidson started for Washington the 1st of January to attend a geodetic conference called together by Prof. T. C. Mendenhall, superintendent of the Coast Survey. With him went Captain E. F. Dickins and Fremont Morse of the same service. Capt. Dickins still remains in the East, but Mr. Morse returned a few weeks ago, and will shortly take up field work, probably in Alaska.

The geodetic conference was the first meeting of the kind attended by the representative field men of the Coast Survey in many years. Only a few scientists were invited to the congress outside of the astronomical and geodetic observers of the survey. The meetings commenced on January 10th, with Prof. Davidson as president and O. H. Tittman as secretary. On 42 days papers were read and discussed, embracing every variety of geodetic work, astronomical determinations, magnetic and gravity observations, and tidal investigation. In addition to his duties as presiding officer, Prof. Davidson read a paper on a new method of determining irregularity of the micrometer screw. This treatise attracted a good deal of attention, since irregularity in the pitch of the screw is one of the most influential sources of error in micrometer work, and one of the most difficult to ascertain by the ordinary methods.

During the latitude variation work on Clay street hill, the professor and his son, Thomas Drummond Davidson, conducted a long series of experiments, with a view to solving this problem, and succeeded in determining the source of error with an accuracy far exceeding the necessities of observation. By request of the Philosophical Society of Washington Prof. Davidson repeated his lecture before that body, and his paper is now being published.

While in the national capital Prof. Davidson visited the new naval observatory, where is housed the great 26-inch equatorial with which Prof. Asaph Hall discovered the two satellites of Mars. He states that the observers were hard at work on every clear night and making the best possible use of their atrocious climate. The geodetic conference had recommended that the star list published by the "Nautical Almanac," under Prof. Simon Newcomb's direction, should be largely increased for the benefit of the fieldmen of the Coast Survey. Prof. Davidson saw the celebrated American mathematician about this matter, and Newcomb cordially indorsed the proposition, and will endeavor to have the star lists improved. Since only those stars, the apparent positions of which are given, can be used from day to day by the field observers, an increase in this list will greatly facilitate the latitude work of the Alaska and other boundary survey parties.

Prof. Davidson had a long conference with Prof. Newcomb also on the latitude question. Prof. Newcomb has from the start been deeply interested in the series of experiments made to determine the latitude variation, and he states that the 4000 separate determinations made by Prof. Davidson in San Francisco are of such accuracy that they may be used not only for the primary investigation, but also to determine a new value for the constant of aberration. This is one of the fundamental constants of observational astronomy, first determined by Bradley in the last century, and steadily improved as the observational methods have been refined since that date.

After a partial recovery from his Washington illness, Prof. Davidson started west-

ward, stopping at New York, Allegheny and Chicago on his way. At Allegheny he made quite a visit with Prof. J. E. Keeler, formerly astronomer at the Lick and now director of Langley's old observatory. He says that Prof. Keeler is doing faithful and conscientious work at his place, especially in the line of astro-physics, studies of stellar spectra, etc. The professor also visited John A. Brashear, the celebrated maker of lenses at Allegheny, who constructed the giant spectroscope for the Lick Observatory. The most interesting thing he learned here was the forthcoming erection of a 30-inch telescope just a couple of miles to windward of the smoky city, where some good work may be done, particularly since the site selected has an altitude of over 400 feet above the river. Brashear has already started upon the lenses, the money for which has already been subscribed by the citizens. When this great telescope (the third largest in the world) is completed, Prof. Keeler will have an instrument to work with worthy of his astronomical skill.

At Chicago Prof. Davidson visited S. W. Burnham, of course. The ex-Lick astronomer, who has just received the gold medal of the Royal Astronomical Society for his double-star work, was deep in the preparation of his great double-star catalogue, for which a congenial court position gives him occasional opportunity. Together Professors Davidson and Burnham visited the Northwestern University at Evanston, Ill., where Crew and Hough are pursuing their astronomical studies. Dr. Henry Crew will be remembered as another Mt. Hamilton astronomer, who found the conditions there unpleasant and accepted the first good offer he received.

Prof. Davidson was greatly interested in Crew's magnificent photographic work on the spectra of stars, several specimens of which he has brought back with him. Prof. Hough showed the California astronomer a new device for controlling the movement of his large equatorial. The new control operates every second and keeps the telescope in absolutely uniform motion, so that the best photographic work is rendered possible.

When Prof. Davidson was asked about the reported attempt to abolish the Coast Survey, his conversation became animated, even for Prof. Davidson. He said that the same scheme, or similar ones, were brought up with each successive Congress, and that he did not believe they could succeed. The leading men in Washington scientific circles heartily approve of the work of the Survey, and understand its importance, and the leaders in the House are in sympathy with the needs of the service.

Origin of Anthracite.

The main difference between anthracite and bituminous coal is that the former is devoid of volatile matter, says an exchange. Heretofore the theory generally accepted to account for this difference was that presented by Prof. Rogers while conducting the first geological survey of Pennsylvania. Observing that the anthracite beds lay in the eastern part of the State, in close proximity to the Archean axis of elevation, he surmised that these coal beds had, so to speak, been "coked" upon the elevation of the Appalachian chain; that is, he supposed that the heat and pressure accompanying the Appalachian elevation, acting most vigorously near the axis, had distilled and removed the volatile matter of coal beds nearest it.

To adjust the theory to increasing facts, Prof. Lesley added the supposition that the heat involved in this theory was brought up by conduction when the superincumbent layers of rock were extremely thick, which have since been mainly removed by the erosive agencies which have been active over the region for millions of years.

The inadequacy of these theories has led Prof. J. J. Stevenson of the University of

New York to propound another and simpler theory, which was ably defended by him at the recent meeting of the Geological Society of America.

He would account for the lack of volatile matter in anthracite coal by the simple fact that it had been longer exposed to that kind of decay which takes place in vegetable matter when immersed in water, and which consists chiefly in the loss of hydrocarbons which constitute the volatile elements in bituminous coal. On this supposition, the anthracite beds are those which were formed earliest in the swamps and lagoons of the carboniferous period, and remained longest devoid of the coverlog of the sedimentary deposits which subsequently preserved them from further change.

This theory is confirmed by the fact that there is no such strict relation of the anthracite beds to the Appalachian axis elevation as Prof. Stevenson is about to publish. This simple cause seems adequate to account for all the phenomena, and probably solves one of the long-standing mysteries of geological science.

Sub-Aqueous Combustion of Fuel Gas.

A mode of generating steam by fuel gas without the use of heating surfaces has been invented by Percival Pickney of Portsmouth, England. His method which is quite novel and likely as impracticable, is described as follows: In the interior of the bare shell of a steam boiler (or in the inside of a suitable casting attached thereto) there is fixed that which has been named "a chamber seating." Upon this tried-up seating rests a conical chamber having an arrangement around its base which causes the two surfaces to form, when in contact, a tight joint, similar to that of a bell glass when used for experimental purposes with an air pump—the cone or combustion chamber being entirely and deeply submerged by reason of its position at or near the bottom of the boiler. There are vertical guides projecting upward from the chamber seating, up which the combustion chamber will travel during its recoil at each explosion. The mode of operating the invention is as follows: A charge of gas fuel having been injected into the inside of the cone it is immediately fired. As the result of the explosion the combustion chamber rebounds upward from the chamber seating, and so allows the heated and expanded products of the combustion to escape direct into the lowest stratum of the water of the boiler in the form of millions of little upward percolations. The combustion chamber having settled down (the guides) and formed a tight joint upon its seatlog, a valve opens, and so economizes even the small amount of residual pressure remaining in the chamber, which is caused to escape into a cylinder connected with the engine, from whence, after performing its duty, it exhausts.

The inventor claims that gas bubbles will ignite during their passage through water; hence, he holds that their sub-aqueous combustion is the solution of the fuel-waste problem. He declares that the loss of mechanical efficiency occasioned by the absorption of energy by the cold water jacket of the cylinder, and the extremely high percentage of energy which, as heat, is absolutely wasted in the exhaust, makes the gas engine greatly inferior to the use of steam generated on his plan. He states that in his motor the same combustion is caused to take place in a sub-aqueous or under-water chamber, from whence the products of combustion escape, not out into the open air, as in the gas engine, but into and at the bottom of the body of the water that is contained in the boiler. Consequently every unit of the heat evolved by the combustion of the gas is absorbed by the water, and thus, for every unit of heat energy evolved by the combustion, there is conserved or stored up its full equivalent of energy in the form of steam. He further claims that ad-

ditional to an enormous volume of steam from a given quantity of fuel he likewise secures and utilizes through the cylinders of the engine the heated and thus expanded air resultant from combustion.

UNION IRON WORKS,
SACRAMENTO.....CALIFORNIA.

ROOT, NEILSON & CO.
—MANUFACTURERS OF—

STEAM ENGINES, BOILERS
And all kinds of
MACHINERY FOR MINING PURPOSES.

FLOURING MILLS, SAW MILLS AND QUARTZ MILLS.
Machinery constructed, fitted up and repaired.

Front St., bet. N and O, Sacramento, Cal.

PIONEER REDUCTION CO.,
NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract, or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ores or concentrates.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are provided. Thus the needs of the scientist and the practical minor civil engineer are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend-Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1890.

This new book on the treatment of gold and silver ore without quicksilver is heretofore illustrated and crammed full of facts. It gives short and concise descriptions of various processes an apparatus employed in this country and in Europe, and the theory and practice. It contains 150 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$3, coin, postage free. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY PUBLISHING CO., 220 Market St., San Francisco.

TUBBS CORDAGE CO.
(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.
611 & 613 Front St., San Francisco, Cal.

School of Practical, Civil, Mechanical, Electrical and Mining Engineering,
Surveying, Architecture, Drawing and Assaying,
723 MARKET ST., SAN FRANCISCO, CAL.
Open all year.

A. VAN DER NAILLEN, President.

Assaying of Ores, \$25; Bullion and Chlorination Assay, \$25; Blowpipe Assay, \$10. Full Course of Assaying, \$50. ESTABLISHED 1864. Send for Circular.

Mechanical Progress.

Testing Cross-Compound Engines.

Some tests made upon cross-compound engines, by George H. Barrus, one of the judges in the department of steam engineering at the World's Fair, are followed by interesting results. The engine treated was of 14 and 28x24 inches, with unjacketed cylinders. The shaft governor operated upon the cutoff on the high-pressure cylinder only. The low-pressure cylinder cutoff is fixed, but may be adjusted by hand to any desired point. The exhaust of the low-pressure cylinder was passed through a Wheeler surface condenser and a Conover independent air pump was used. The engine was employed in driving a line shaft, to which was belted numerous dynamo machines generating current for electric lighting. The tests were five in number. The first three were made with three different loads, and the cutoff of the low-pressure cylinder fixed at a constant point, which was approximately at one-third stroke. The fourth test was made with an earlier cutoff in the low-pressure cylinder, and consequently a higher receiver pressure, the load being approximately a mean between that of the first and second tests. The fifth test was made with the engine running non-condensing. Steam, however, was still carried through the surface condenser, so that the quantity consumed could be measured by means of the weighing apparatus.

At the close of the trial the valves and pistons were tested for leakage, and the engine was found in rather an unsatisfactory condition in this respect; in fact, Mr. Barrus estimates that the steam consumption was increased not less than one pound per horse power per hour by this defect. A notable feature of the test was the fact that the engine rated at 300-horse power and with a load of 123.39 indicated horse power, or 41 per cent of the nominal capacity, used only 7 per cent more steam per horse power than it did when working at its rated power. The plea is sometimes made that a compound engine is not well adapted to situations where the load is variable, owing to its wasteful use of steam when working at small powers. The results obtained in this case indicate that the compound type of engine shows less fluctuation of economy than might be expected from a wide change of load. Indeed, the difference exhibited is remarkable for its small amount, and this good showing must be gratifying to those who advocate the unrestricted use of compound engines.

A New Quick-Firing Gun.

The new Salvator mitrailleuse, or quick-firing machine gun, having been adopted by the Austrian military authorities, a number of pieces have been manufactured and are reported to be ready for distribution, says the *Scientific American*. The gun is not intended for use in the field, as in the case of the English Maxim and Nordenfeli machine guns, but will be mounted stationary on the outworks encircling important fortresses. It is said to be only half the weight of the Maxim, and its average rate of discharge is about the same—300 rounds per minute, with a maximum of 320. The diameter of the bore is eight millimeters, being similar to that of the Mannlicher repeating rifle now in use in the Austrian service. The barrel is not incased in a water-jacket, and 1200 continuous rounds can be fired before it shows the effects of the excessive heat. The cartridges are supplied, as in the Nordenfeli, from a large hopper fixed above the firing chamber. The gun is fired by means of an ordinary trigger, with trigger grip, and a recoil spring supplies the automatic action. But the principal point of interest in respect of which the new gun differs entirely from the mechanism of similar weapons now in use in

other countries is the oscillating pendulum regulating the speed of fire. There are two firing commands with the Maxim—single fire and continuous fire. The discharge is regulated by the turning of the crank handle. The single fire is as the fire from an ordinary repeating rifle, while continuous fire represents the most rapid discharge of which the machine is capable. With the Salvator mitrailleuse, however, the great advantage is gained of sustaining a moderately heavy discharge of 30, 50 to 100 rounds per minute, and increasing it by means of a faster oscillation of the pendulum to 300 when a dangerous phase of attack has been developed.

Tensile Test of Wrought Iron Axles.

As previously named, a reduction appears to have been made on the original limit of tensile strength required by the new regulations of the railway companies for steel axles, viz., from 40 tons per square inch to 35 tons per square inch; but no modification has yet been made in the case of wrought-iron axles, says Thomas Andrews in the *Engineer*. The author therefore suggests, in the interest of safety—in order to prevent subsequent brittleness arising in the case of wrought-iron axles—a modification in the tensile strength of the iron axle from 22 tons to 20 tons per square inch. For all practical purposes the efficiency of railway axles is more than amply assured by the excessively severe drop test, which, in the author's opinion, is in excess of all reasonable requirements for either iron or steel axles.

The author, however, ventures to suggest, for reasons previously given, that the test for wrought-iron railway axles should be as follows: The axles to be capable of standing the following test without fracture, viz., five blows from a weight of 2000 pounds falling from a height of 20 feet upon the axle, which shall be placed upon bearings 3 feet 6 inches apart, and turned after each blow. After the fifth blow the axle to be broken. Also, each axle to be guaranteed to stand a tensile strain of not less than 20 tons per square inch, with say 25 per cent (or not less than 20 per cent as a minimum) of elongation; the test length to be three inches.

It will thus be seen from the above suggestion that the tests are proposed to be about equal for both iron and steel axles, i. e., as regards the tests of impact and elongation. With regard to the breaking strain per square inch for wrought-iron axles, it is only proposed for reasons stated in this paper—to be brought more in consonance with the nature of the metal obtaining in wrought-iron axle forgings, as ascertained from the results of actual past experience.

Stamped Steel Chains.

Attempts have been made from time to time to utilize steel for chain making, and in one of the later inventions in this direction a chain is produced out of bar steel each link being formed solid and linked in with its neighbors, says the *Age of Steel*. In the manufacture the steel has to be heated, and although an excellent chain is produced, the links are what are called open links—that is, they have no stay or cross-piece as in links of the cable pattern. Stays are added afterwards, but they do not form an integral part of the link. A subsequent inventor, M. Rongier, has, however, succeeded in forming a stay or stud with the link itself, the chain being stamped out of the solid bar, and this appears to give the finishing touch to the manufacture of weldless steel stamped chains. The method of production is very ingenious, and has been in operation at the works of the Patent Weldless Chain Company at Aston, Birmingham, England. The chain is made from a steel bar of cruciform section, and of the greatest length obtainable. This bar is put through a series of machines, in each of which pieces are punched out, so that after five operations

the links are perfectly formed, but are still connected together at the point where the inner side of the bow of one link crosses that of the other. In fact the bar represents a rigid chain, but on being passed through another machine it comes out a roughly formed but perfect chain with separate links. The chain then undergoes three more operations in which it is rectified, rounded, and finished ready for use. The process is a cold one, so that there is no deterioration of the metal by heating, the only heat applied being near the end of manufacture, when the chain is annealed in an oven for a short time. Owing to the limited length of the bars the chain has to be made in sections, and eventually coupled by special links, which are made stronger than the chain itself. These chains, which are suitable for general use, are produced in various sizes, from ½ inch down to 3-32 inch.

THE TECHNO-CHEMICAL RECIPE BOOK:

Containing Several Thousand Receipts, covering the latest most important, and most useful discoveries in the Arts and the Industries. Edited chiefly from the German of Dr. Winckler, Emsen, Heinze, Mierzinski, Jacobsen, Koller, and Heinze, with additions by Wm. T. Brandt and Institute, Philadelphia. Illustrated by 78 engravings. On cloth, gilt, closely printed, containing an immense amount and a great variety of matter.

Price \$2.00, free of postage to any address in the world.

A circular of 32 pages, showing the full Table of Contents of this important book, sent by mail free of postage to any one in any part of the World who will furnish his address.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$4.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.
This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep veins, and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdy, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' tools, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

J. F. CROSETT, Commission Mining Agency.
628 Sacramento St., San Francisco, Cal.
Buy and Sell Meritorious Mining Properties. I have orders for Income-Paying Mines at the present time. Have also some good properties for sale. I want more mines to offer to purchasers and also desire more purchasers to examine properties I have to offer. Correspondence solicited.

LIGHTNING WELL MACHINERY Works.
All kinds of tools. Fortune for the driller by using our Adamantine process can take care. Perfected Economy. Let us help you. THE AMERICAN WELL WORKS, Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

Electricity.

Electric Lighting in Europe.

In W. McDewitt's report as expert to the Philadelphia Fire Underwriters' Association and Philadelphia Fire Patrol, regarding electric lighting in Europe, we find the following interesting information regarding European methods:

A very striking feature is the absence of poles in the streets of the cities visited. The lead set by the Government in placing telegraph wires under ground has been followed, and this has been the more easily done as the demand was small. Telegraph cables are drawn into iron pipe conduits with conveniently located draw-boxes. With low-tension currents considerable trouble arose from the use of insulated wires. Bare wires are now being experimented with, set in terra cotta or wooden conduits, and strung in the latter on porcelain insulators. The most severe high-tension work, that with the alternating current from Deptford, at 5000 volts, with 10,000 in case of a breakdown, is done with the Ferranti concentric mains, consisting of two copper conductors, the inner one insulated from the outer containing one by a heavy paper insulation. These are carried in the railway viaducts to a sub-station, and then with reduced current under the streets to distributing points. For ordinary 1000-volt alternating work good rubber-covered wire is used, drawn into conduits of different materials, but chiefly of wood.

Most of the conduits are under the sidewalk. The streets are too well constructed to allow of the continual opening we have in America, and it has been found cheaper and easier to confine the openings to the sidewalks.

Distribution by alternating current is usually done from underground distributing centers, current being taken from one large converter to the different buildings—a simpler plan than the separate building, separate converter plan.

No high-tension arc-light currents are used in buildings; they are confined to street lighting. This is due partly to the Board of Trade regulations and partly to the status of electricity as more of a luxury, while here it is a necessity and has not to compete with such cheap and excellent gas as that burned in Europe. Arc lighting in buildings is effected with low-tension arc lamps on incandescent circuits, the lamps being very handsome and closed in at both top and bottom.

Stranded wire, for all sizes above No. 18, Birmingham gauge, is used, although more expensive than solid wire and the insulation less liable to crack when the wire is sharply curved.

There appear to be no uniform rules for installation, each insurance company making its own inspections. The station buildings are all substantial with timber hard and solid, partition walls, stone stairs, substantial plastering, and they are generally very solid, showing that the fire risk and durability were both carefully considered. All wires are insulated with the best quality of rubber, but less care is taken with the wiring, staples being largely used.

Interviews with insurance companies and contractors prove that they have experienced as much trouble in Europe as we have here from defects in installation. They are learning fast, however, and profiting from our experience.

Electroplating a Ship's Bottom.

Every one familiar with nautical affairs knows that various marine growths, animal and vegetable, attach themselves to a ship's bottom; and that most vessels, therefore, need to be banded out periodically to be cleaned, says an exchange. To wood, steel and painted surfaces these parasites adhere

so firmly that mechanical means are required to remove them; but from copper they are washed off by motion through the water. Hence, the expense of frequent cleaning, and the great impairment of speed resulting from these growths, are averted by sheathing a vessel with this metal.

It is a cumbersome process, however, to apply the copper to steel hulls like those of the new navy. First, the vessel must be covered with wooden planking, two inches thick, bolted to the plates; and then the copper has to be riveted on to the wood. The two metals cannot be brought into direct contact so long as complete union is not effected, because destructive galvanic action would be thus induced. Thomas S. Crane, in view of these facts, has invented and patented the idea of coating steel vessels with copper by electroplating; and he has found a way to utilize this process without submerging the whole ship in the chemical bath, as is done with small articles that are plated with nickel or silver. He fits a box up with an elastic frame against the side of the vessel (which must be in a drydock) in such a way as to have a water-tight joint, and so that he can electroplate a section about 4x10 feet square; and when this is covered to a proper thickness, as it is in about 70 hours, he moves along a little, like a house painter, and coats another section. It is practicable, of course, to have a number of these boxes or tanks in service at one time. Where the sections overlap, the coating is continuous, like paint, and the copper adheres to the steel as firmly as if they were welded together.

Upon a vessel 400 feet long and drawing 20 feet of water the work can be done in eight or nine days, by using 60 baths on a side and having 780-horse power behind the dynamos. It has been estimated that the surface of such a vessel would amount to nearly 24,000 square feet; that 55,500 pounds of copper (at 12 cents a pound) would be required, and that the metal alone would involve an expense of about \$6660. Eighty tons of coal probably would be enough; and at \$4 a ton this would raise the bill to nearly \$7000. And then something would have to be added for the plant.

Underground Electric Conduits.

Of the large number of underground electric wire conduits which have been used or proposed, there are at present in successful use in America, on a large scale, four typical forms: Iron pipe, which may be either cast or wrought; cement-lined sheet-iron pipes; terra cotta or clay pipes, and wood tubes.

The most generally used are the earthenware conduits, and the most used of them are made of glazed terra cotta in sections three feet long, with one or more rectangular ducts, each capable of carrying at least three cables. Prof. D. C. Jackson, in *Cassier's Magazine*, says that in Milwaukee an ordinary cement sewer pipe has been made in the same manner as the tile, with cemented joints, and it makes a very fair conduit, which is a little cheaper than the special forms. The pipes are softer than vitrified tile, and, therefore, more liable to mechanical injury, but the system has not yet been long enough in use to fully decide on its comparative merits.

The simplest of all conduits, and one which is used quite generally, is a common wrought-iron gas or steam pipe, either laid bare in the ground or in a bed of concrete. Ducts are usually of two-inch or three-inch pipes, and since a three-inch pipe will carry four ordinary electric-light cables, the system is economical of space in the streets. One cable can be pulled out when the others are in the ducts, but the practice of handling cables separately when several are in one duct is not advocated by the most experienced. Joints in the pipe are made with a sleeve screwed on with a vanishing

thread, which is cut so that the ends of the pipe come close together inside the sleeve. The sections of pipe are generally 20 feet long. The great advantage iron pipe has over all other forms of conduit is its flexibility. It may be bent in any direction at any point, to avoid obstacles in the streets, and it should always be used when obstacles are particularly numerous. Some authorities claim that a conduit should never bend, but experience in New York and Chicago proves that cables can be pulled easily around several bends with radii of three feet or less.

Tubes of wood, treated with various substances to preserve them, have been manufactured by several companies and quite generally used. At present Philadelphia probably has in use a greater length of wooden conduit than any other city, though there is considerable of it in Chicago and Brooklyn. The commonest form of wood conduit is made up of four-inch by four-inch pieces of wood, with a three-inch hole bored through from end to end. They are joined either by a male and female union or by simply butting the ends together.

A cement-lined iron-pipe conduit consists of a tough sheet-iron shell, riveted and lined with five-eighths of an inch of pure cement, no sand being used, and the inside being carefully smoothed. The pipes are made in eight-foot lengths and of various diameters.

All of these conduit systems are in successful operation on a large scale, but the period of use has not yet been long enough to prove positively that they will all endure satisfactorily. The users of each appear to be well satisfied.

Useful Information.

A Word to the Sleepless.

Dr. J. E. Huxley of Maidstone, England, thinks he has hit upon the natural remedy for sleeplessness. It is, in brief, to curl under the clothes like a kitten, or put the head under the wing like a hen. He says: "This insomnia seems to be now a universal affliction. We live wrongly, sit up late, and overwork the brain, and then go to bed in an excited condition. No one seems to have hit upon the natural remedy. I think I have. People take chloral and the like at their peril, and the fatal consequence not seldom ensues. It is all wrong, for you cannot control the dose required for the exact circumstances. But try nature's plan instead: lower the supply of oxygen to the blood, produce a little asphyxia, limit the quantity of air to the lungs, and heart and circulation becoming quicker, the brain loses its stimulant and sleep follows. When you find yourself in for a sleepless night, cover your head with the bedclothes and breathe and rebreathe only the respired air. Thus you may reduce the stimulating oxygen and fall asleep. There is no danger. When asleep you are sure to disturb the coverings and get as much fresh air as you require, or, when once drowsiness has been produced, it is easy to go on sleeping, though the air be fresh. What do the cat and dog when they prepare to sleep? They turn around generally three times, and lastly bury their noses in some hollow in their hair, and 'off' they go. They are in no danger, although it might look as if they were from the closeness with which they embed their noses." From the Medical Press and Circular.

Estimating the Sulphur in Coals.

A method whereby the sulphur in coals may be estimated and their suitability for gas making determined before purchase, has been introduced by Herr W. Hempel, an authority on coal gas in Germany. The coal to be tested is powdered and pressed into a little platinum wire cylinder, to which a long platinum wire is attached, and then

burned. The combustion is effected in an ordinary glass bottle, which is fitted with a treble perforated india-rubber stopper. Through this passes a tube with a glass stopcock, and which widens out into a cylinder; also two glass tubes, to the lower ends of which two thick platinum wires are fused. One of these wires carries the platinum cylinder or basket already referred to. A little mercury is poured into the tube so as to establish sure contact with the wires which lead the electricity. When the current is passed the platinum basket becomes white hot, the combustion of the coal is effected, and the gaseous products containing the sulphur compounds are led off through the stopcock and examined chemically. This is practically an improvement on the more complex method originally devised by Berthelot.

Ventilation.

An address was given before the Yorkshire Engineering Society recently by Prof. Ernest H. Jacob, M. D., on the subject of "Ventilation of Buildings." The lecturer stated that six parts of carbonic acid gas were not obnoxious, but 12 parts in 10,000 gave rise to objectionable odor. He showed by means of transparencies the course of fresh air entering hot rooms; that the greater part of the air in supposed circulation is really stagnant, and that this stagnation very usually extends beyond the limits of the breathing line. Consequently the admission of cold air at the base of walls, with exit from the ceiling line, does not necessarily ventilate the room. Touching upon the propulsion and suction systems, he remarked that there are objections to the long air passages of the former system, and showed how the useful area of such passages may be considerably reduced by sharp bends. In pipes with elbows at right angles the reduction of available area is as much as 25 per cent. Some of the best ventilated buildings are those fitted with both propulsion and suction fans. For efficient means of ventilating and heating, he urged that heating radiators should be arranged, so that the incoming cold air could be drawn over the radiators if necessary, or deflected partly over the coils or not at all. It was thought to be better to arrange the heating coils in sections, so that part could be cut off from the heating supply. If the temperature of the air on passing over the coils was greater than that of the air in the room, then it would rise, and in order to promote its circulation it should be drawn away from the base of the opposite wall, to which it enters. If, on the other hand, the air was colder when entering the room, it should be drawn away from the ceiling line of the room. These differences occurred in summer and winter, and air valves should be arranged accordingly.

Curious Egg Tricks.

Some curious tricks can be performed with eggs prepared in the following way: Pierce an egg with a pin and empty the contents of the shell. When the interior is quite dry, pour into it some fine sand until a fourth of the shell is filled. Then seal the hole with a drop of white wax. You can then place the egg on the edge of a knife or the margin of a decanter, and it will stay where you put it. Take care to shake the egg well before placing it in any of these positions, and thus bring the center of gravity to the place where you desire it to be. To make a disobedient egg, introduce into an empty egg shell some grains of shot and sealing wax. Close the hole and hold the shell over a flame until the wax inside has melted. The shot and wax will then adhere at the bottom of the egg. When cool, place the egg on the table and it will stand upright. The egg will be a source of mystery to your friends, as it will refuse to assume any other position.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents of the Denver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Opinions free.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight riffling surface for the space of three inches, which tends to equalize the pulp on the belt, and prevent it from banking on the sides and forming channels through the center. These slight riffling also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

WRITE FOR CATALOGUE No. 00

Reviewing some FIFTY of our Publications in English, French and Spanish.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes thereof by knowledge from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Ore; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Copper; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutions and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Vohler's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market St., San Francisco.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs in the shaft. SPECIAL CONSTRUCTION OF STEEL only one-eighth part the weight of the old pump. Works with 10 per cent less power. First outlay one-third less. Suitable to any underly or downright shaft. Occupies less space in the shaft. Has been tested a year and proved to work satisfactorily in every respect. GLAND OF STUFFING-BOX TIGHTENED AND ROD LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING OR BUCKET PUMP.

Bucket, clack and clack-seating changed under water. Bucket lasts six times as long as the old bucket, often saving expense of putting down another pump, especially in jack-head pumps, where bucket and clack cannot be changed under water. Special attention is called to the self-tightening stuffing-box and new bucket which obviates the expense and delay of frequently dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, Cal.**THE GRIFFIN MILL.**

A perfect pulverizer of all refractory substances by either the wet or dry process. It works better and at less expense than any other Mill, and is conceded to be the only perfect pulverizing Mill Manufactured.

**FOR TOWN WATER WORKS.****Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.**

NO. 180 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Mining Summary.

The following is mostly condensed from journals published in the Interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE AMADOR GOLD.—*Ledger*, March 23: The litigation concerning the possession of the Amador Gold mining property seems to be only at its commencement. Vincent Neale, the present holder as a redeemer of the sheriff's deed in the sale under the decree of foreclosure of the lien actions, being satisfied of the correctness of the decision in the Superior Court denying his motion for a writ of assistance, has decided to take no appeal from it, but instead, on Saturday last, filed in the clerk's office a petition for leave to file a supplemental complaint in the nature of a bill of revivor in the original lien actions.

An examination of the complaint filed presents an interesting question of law. After setting out in full the history of the foreclosure suits against the Amador Gold Mine, Limited, it recites that the Amador Gold Mine was the predecessor in title of the Amador Gold Mine, Limited, and claimed title to the property during all the time for which liens were claimed as being done, and never gave notice that it would not be responsible for the payment of it, and also that the motion for a writ of assistance to dispossess the Amador Gold Mine was denied on the ground that the Amador Gold Mine was not a party to the lien actions, and was therefore not bound in the decree obtained in them. Mr. Neale therefore asks that the sheriff's deed be set aside and that he be allowed to file a supplemental complaint in the original foreclosure actions to include the Amador Gold Mine so as to bind it by the decree.

The Hardenburg was shut down several days and work was commenced again Thursday afternoon. The shut down was occasioned by the mine making more water than the hoist could handle. They have encountered a small bunch of rock in the north drift which they are following in the hope that it will become permanent. On the surface they are doing some grading for a new hoist.

The New York mine, formerly the property of Anderson & Stewart, has been reorganized under the name of Evening Star Mining Company. Mr. Anderson will still remain superintendent, and it is intended to commence work upon the 1st of April.

The Gwin mine proposition is in good shape, and work will commence there upon the 1st of April.

Butte.

SINKING ANOTHER SHAFT.—*Forrestown News Era*, March 22: The owners of the Golden King mine, Messrs. Quick, Crossman and Ky-nock, are sinking another shaft on their ledge. This shaft is being sunk at the northern boundary of their location, just below the schoolhouse. They are now down 30 feet and have had the ledge for 20 feet; it is about four feet wide. The rock shows well in sulphurets and carries considerable free gold. This company has now three shafts on their location, one at each end and one in the center, and in all of these they have found the ledge, with the same kind of rock and about the same width. The company will follow the ledge down some distance in order to ascertain the true pitch, so as to obtain the basis for starting a tunnel to tap it at a much lower level. It is proposed to start a tunnel below Main street. The tunnel will have to run between three and four hundred feet before it will tap the company's grounds, at the extreme northern point and at a depth of 250 or more feet. It is also thought that enough rock will be taken from the shaft to have a milling test made of its value. This is one of the easiest mines to work to be found in the district, as it runs along a sidehill, following a ravine the entire length of the location, and can be tapped by tunnels from the ravine at almost any point and at considerable depth.

Much development work on quartz locations is now going on in this vicinity. The closing down of the Shakespeare and Golden Queen mills released quite a number of workmen who have been putting in their time prospecting ledges located by themselves. Some good rock has been found. With the putting of men at work on the Shakespeare mine and the starting up of the Golden Queen mill, many of these prospectors will find employment, but the work they have done on their locations will be of great benefit in determining the value of many ledges, and will probably enable some of them to make a sale of their property. Taking the camp as a whole, the outlook for a lively summer was never better.

It is reported that work at the Shakespeare mine is about to be resumed. This, if it should prove true, is good news, as it will give employment to quite a number of men and greatly revive our camp.

Reports from the Bullion mill are very encouraging. Under the skillful charge of Mr. Peterson, as amalgamator, good returns are being realized.

The Denver mill is being run to its full capacity and, as far as we can learn, with very satisfactory results to its owners.

The development work at the Golden Queen mine is in good ore, and it is quite likely that the mill will soon be running again.

The Beehive mill, at Mt. Hope, has not yet started up, but work is progressing very favorably at both mine and mill.

Calaveras.

AT THE ECLIPSE.—*Echo*: In this mine the shaft is 189 feet deep, and crosscutting east and west from the shaft is now in progress. Mr. Flagg, the superintendent, informed us that he

believed the ore body would soon be tapped, and when this was done he would give us information that would astonish the natives. The Eclipse is a good mining property. The stockholders of this corporation need not fear of developing a good mine. It is there, and if they continue in their onward march they will sooner or later realize the benefits that shall accrue from their output.

THE GWINN BOND.—*Amador Record*: F. F. Thomas, Hon. Wm. M. Gwin and David McClure, J., were in Sutter Creek last week as guests of Senator Voorhies. On Saturday they all visited the Gwin mine, which is located just across the Mokelumne river, below the Big Bar Bridge, with a view to taking preliminary steps for opening the mine in a systematic manner.

The property has been bonded to Mr. Thomas for four years for \$100,000. Machinery will be put on capable of sinking the shaft 1500 feet. Mr. Thomas and his associates are negotiating with the Blue Lakes Water Company in anticipation of securing water from the Amador side for electric power at a small outlay. The water company owns a site with a fall of 1000 feet, just below the Big Bar bridge, where dynamos, etc., can be located. It is estimated that the cost of the necessary apparatus for generating electrical power would be from \$10,000 to \$15,000, and if this is found to be less than water can be obtained for from the Foreman ditch, in Calaveras county, this plan will be adopted.

The Gwin mine has not been worked for the past thirteen years. Owing to mismanagement and inadequate machinery, water was allowed to accumulate and the underground workings became so dangerous through cavings that work was abandoned, the owners not having money enough left to handle the property. The chute of ore in the mine was over 1000 feet long and of good width. The shaft at the time of the abandonment was down 1300 feet, and it is proposed to pump and clean this out and sink it to a further depth of 200 feet.

The reopening of this mine is not altogether an experiment by any means, as it has been explored sufficiently to demonstrate the existence of a large and valuable body of ore. There has been talk at frequent intervals for several years of the mine starting up, but until now no active steps have been taken in that direction. Mr. Thomas, the holder of the mine, has the financial backing, the experience and the energy to develop the property for all it is worth. His career as a mining superintendent has been a brilliant one. After organizing the present Kennedy Company and reopening that now bonanza mine, in which he is still interested, he went to Australia, where he assumed the management of a silver mine. In a short time he had the property on such a paying basis that the stock increased in value from \$2.50 to \$75 per share. He was soon superintending three mines and receiving a princely salary. Within two years Mr. Thomas' signature was good at a bank for over \$100,000, and it is said that when he returned to Amador county he brought with him at least a quarter of a million dollars. He told a friend that if he had had a few thousand dollars to invest when he first went to Australia he could have cleaned up a million dollars in a short time.

It is calculated that an expenditure of about \$75,000 will be required to properly open up the mine. Jackson will be the base of supplies and the principal headquarters of Mr. Thomas and his employees.

THE NEW HOSPITAL.—*Echo*: The new hospital now being erected in this town on South Main street is nearing completion. The building is 40x40 feet and has a basement nearly in equal proportion. There are two wards, ample to accommodate eight patients. All the modern appliances pertaining to a hospital will be put in this building. Patent closets 6x6 are being constructed, and the very latest styles of washstands are being put in the wards, in fact throughout the building. Dr. J. R. Dorroh is doing the general planning of the building and the architects are following his instructions. Dr. Dorroh was instrumental in having this building erected, and upon his wise suggestion the Utica Mining Co. is having the work done.

Humboldt.

NEW RIVER CAMP.—*Blue Lake Advocate*: Latest news from New river mining camp is to the effect that the Sherwood is not running, on account of the delay in settling up the estate of young Wils. Sherwood, who was accidentally killed last July while celebrating the Fourth, he, it appears, having been the principal owner of this valuable mine. As soon as all probate business shall be settled, operations on the claim will be resumed.

The Boomer still maintains the rank as one of the best mines in the camp.

Inyo.

GOLD ORE.—*Index*: At each of eight claims in Fish Springs district there are now on the dumps from 15 to 30 tons of gold ore, assaying in gold from \$40 to \$80 per ton, which does not include the value of the sulphuretted ore which abounds. There is a fine opening there for some enterprising millman to put in modern works, with thousands of water power to run them. The boys could then keep on mining and let their four ancient arrastras rest.

Kern.

REDROCK AND GOLER.—*Inyo Index*, March 23: From Jake Schober, who returned Tuesday evening from the gold fields, we learn that matters there are quiet. But little work is at present being done in the forty or fifty dry washes, as the ground is too wet. Many of the stories told of the richness of the mines are greatly overdrawn. Three or four of the Schroder and Brockman claims, which number seven in all and are four miles west of Goler, have been prospected enough to prove that they will pay \$5 a day to the man. At that

point bedrock is found from six inches to three feet under the surface. A. Cruee and Mih. Hall are working in the vicinity, and Clark, Drake, McDonald and Wilder, of Bishop, are prospecting. H. A. Burgess has several claims, one of which he has lately bonded for \$800. One of the richest claims is owned by a number of Mexicans, who take out from \$50 to \$100 a day. At Iuyo Canyon, Redrock, Sullivan & Black have ten men at work, and will soon double this force. The gold taken out in the camp is sold for \$17.50 per ounce. The principal settlement is at Redrock, where there is a store, a restaurant and a saloon, and eight or ten tents. At Sullivan & Blacks there is a store and a saloon and fifteen or more tents. At Miller's stage station there is a store and a saloon, and Bonanza Gulch has half a dozen tents. These are all within a mile or two of what is termed Redrock, which is 18 miles from Goler. Two petitions have been circulated for the establishment of postoffices there. There is no use for anybody to go to that country expecting to find claims, as the most of the country is said to be located for sixty miles off east toward Death valley. Asa Hall has struck a deposit of colemanite, or crude borax, near Goler.

Nevada.

BONU ON THE BOSS.—*San Juan Cor. Herald*: The bond on the Boss mine expires some time during the next 30 days. The parties to whom it was bonded will doubtless be on hand and in readiness to take the property, and will, without doubt, profit by the transaction, as they have had it bonded for nearly six months, during which time they have demonstrated that this mine can be made a dividend paying mine. Although the ore is of low grade, the vein is an extensive one and the ore is easily mined and milled. A larger plant will probably be put up on this mine, which will bring the long looked for good time to San Juan and vicinity.

GOOD ORE.—*Grass Valley Telegraph*: Mr. Martin Lahey brought some very good ore to town and was showing it around among miners and mining men generally. The ore came from a ledge owned by Mr. Lahey, and is located at Allison Ranch. The rock came from the croppings and it showed fine gold freely.

GEANITE HILL MINE.—*Telegraph*: Superintendent Denver Waggoner informs us that work is going on finely out at the Granite Hill mine. They are so rigged now that they are lowering the water rapidly, and have got it down to a depth of 160 feet.

OSBORN HILL MINE.—*Telegraph*: The mechanic and mill-builder who has been in the employ of Mr. Grayson for a number of years is now engaged in selecting machinery for the new 20-stamp mill to be placed on the mine. Mr. Grayson informs us that the mill will be built as soon as the lumber and machinery can be obtained, and that when completed it will be as fine a mill as there is anywhere.

GASTON RIDGE MINE.—*Telegraph*: The Gaston Ridge mine will soon be worked in an active way. The Gaston Ridge has lately been called the California and is near Graniteville, and Patrick Foley was the superintendent. Alvinza Hayward and other capitalists are interested in the property and they will soon put a sinking plant on the ledge and will develop it to its fullest extent.

RICH STRIKE AT THE PITTSBURG.—*Transcript*: A rich strike was made at the old Pittsburgh mine, near this city, on Saturday. A fine pay shoot was encountered on the 500 level, the rock from which shows considerable free gold and sulphurets of high grade. Specimens of the quartz were being exhibited in town to day. Some very rich rock was taken from the Pittsburgh years ago, but the pay shoot was worked out; and, although a great deal of prospect work has been done there since by other companies, the results in the main have not been very satisfactory.

A QUARTZ BOOM.—*Transcript*: Quartz mining has a boom at North Bloomfield, and considerable prospecting is being done in that section. New locations are being made every day. The Busy Bee Company and the White Diamond have found good pay rock and are employing several men. The White Diamond Company have ordered a new pump, which is expected to arrive any day. The district heretofore has been considered a poor one for quartz, but developments now being made indicate that there is good rock in some places and it is thought this branch of mining will yet assume respectable proportions.

Plumas.

QUINOX MINING AND WATER CO.—*National Bulletin*, March 24: The first of the week, by courtesy of Messrs. Jas. O'Brien, W. C. Ralston and A. B. White, directors of the Quinox Mining and Water Co., we visited the scene of their proposed operations and examined the work done in and about the mine, particularly the restraining dams erected and the dumping ground for the debris. Last year these gentlemen purchased the ditches, reservoirs and extensive gravel deposits owned by the old Plumas Mining and Water Co. and situated near Spanish Ranch, the center of one of the best gravel-mining sections of the State. The system of reservoirs and ditches covers and controls an immense area of rich gravel deposits, about 2200 acres of which the company now owns. In these, undoubtedly, there are millions of money awaiting extraction by the hydraulic process. During the past six months the company has been very actively engaged in putting everything in readiness for operations this spring. For a time it employed directly about 70 men, and many more indirectly, thus expending a great deal of money, probably \$25,000, up to the present, most of which has been scattered among the farmers, laborers, teamsters and business men of Plumas, much to their benefit and the general prosperity of the county. The company will have, during the

coming spring and summer, about 25 men in its employ continuously, and during the time consumed in erecting the large stone dam at the Devil's Elbow, many more hands will be at work.

The mining to be done the coming spring and summer will be confined to Gopher Hill. To restrain the debris and avoid any possible damage to the lands of this valley, a series of four restraining dams has been constructed. The longest and most massive dam is near the mouth of Wapuansee creek, and consists of two parallel walls of big logs, 265 feet long, tied together and filled in between with rock and brush.

In the center of the ravine this crib dam is 11 feet high. The whole structure is a model of strength. The massive logs at the bottom are lying on and bolted to the bedrock.

Each successive layer of logs is bolted to that underneath. The ties are also bolted. Two tons of large iron rods were used by the company in building the four dams. In structure, the other dams are similar to the one just mentioned. We see no possibility that they will give way. They are intended to restrain such material as may be washed down from the main dumping ground above them—to act as settling dams for the finest material, thus preventing any injury to lands in American valley during the coming season, until the erection of the large stone dam and spillway at the Devil's Elbow. Above all of these dams in Wapuansee lake, so called, is a large area, probably a third of a mile long and one-fourth of a mile wide, which will form the main dumping ground to be used by the company this season. This, by the use of flumes, will be filled up as occasion requires, and the debris from the mine most effectually stored where there is no possibility for it to get away, even if there was a far greater quantity of water in Wapuansee ravine than there is. On parts of this flat is now stored debris, probably 100 feet deep in some places. It has not moved—cannot move; it has become cemented or solidified to a large extent and will remain there.

The Quinox Mining and Water Co. has just completed 600 feet of sluice boxes of a very substantial character, four feet wide. The bottom is lined with rock to a depth of about 14 inches. This rock lining will take the place of blocks, and is considered far superior to them. In Placer and Nevada counties, rock lining is used almost entirely. Above this fluming is about 1000 feet of bedrock tunnel reaching up to the gravel banks, which are about 150 feet high. In the claim are six "giant," large and small, to be used at different points. These are supplied from a main pipe 22 inches in diameter, under 350 feet pressure. Of 22, 15 and 11-inch pipe, there is on the claim 3300 feet.

The Commissioner came as far as Beckwith last Friday, but Dr. Leonard gave them such an impression about getting over the road from that place to Quinox that they concluded to defer the trip a few days until the roads improved, and accordingly they went back to San Francisco. They will return here in a short time, pass upon the restraining works erected by the Quinox Mining and Water Co., and if these prove satisfactory, grant the license to mine.

Riverside.

LAKE TIMBERS.—The largest timbers ever shipped to southern California were sent from Riverside to the Good Hope mine, near Perris, on the 8th instant, by the Russ Lumber and Mill Company. They were 26x29 and 32 feet long and four in number. They will be used in the foundation of the new 20-stamp mill. The erection of the mill will consume 100,000 feet of lumber, and seven teams are now engaged in hauling it to the mine.

San Bernardino.

A RAILROAD NEAR.—James Campbell has returned to Los Angeles from Needles and Vanderbilt, two places that are now attracting some attention. Mr. Campbell says that the Nevada Southern Railroad is in good order and regular trips are made to Manvel, which is four miles from Vanderbilt. Two mills are now being constructed—one by Mr. Campbell of Salt Lake City, and the other by Messrs. Paten & Taggart will be in running order within a week. These mills are complete in every particular, and will be a credit to the owners. The mines on which these mills are erected have been fully tested by milling process in Denver, Pueblo and other places. The owners have no fears of the result from their own mills, and have estimated that the ore in sight will keep them running for one year and the average value at \$60 per ton, which goes to show that when the Nevada Southern is finished to the Keystone mill, more stamps will be added to the present mills and new mills and smelters constructed. There is now a party of engineers and a gang of men and scraper teams at work between Manvel and Vanderbilt.

STAMP MILL STARTS.—*Shaft*, March 15: The announcements made last fall by A. G. Campbell and by Patton & Taggart that upon the property of each a ten-stamp mill would be erected was hailed with delight generally. The culmination of hope occurred, however, when Campbell's mill started last week and anticipation was turned to realization. The first clean-up, which occurred after a 40-hour run, resulted in a \$500-bar of gold, 950 fine. The concentrates for the 40 hours will yield \$150. The tailings went \$240. The mill is a ten-stamp Fraser & Chalmers mill. The stamps weigh 750 pounds each, have a seven-inch drop and they drop 90 times per minute. The mill is fitted with Evans concentrators. The power is furnished by two 50-horse power boilers and a 100-horse power engine.

THE BOOMERANO.—W. F. McAdams, the genial foreman of Campbell's mines, almost fainted away the other day when he went down to the 260-foot level in the Boomerang and found that a vein of rich ore over three feet in

width had been opened up. The vein still continues to be of that width.

V. M. AND M. COMPANY.—When the main shaft of the Bronze had reached a point about 50 feet below the lower level last week, Foreman Sauerbrey noticed that the ore was of a different character and took a specimen to the surface, which, when assayed, showed a value of \$1117.38 per ton. The next day he took two samples, which he selected carefully in order that he might get only an average. These two samples with the other made an average of \$342.62 per ton in gold. The character of the ore remains unchanged. The mill at the Bronze will be running very soon.

THE ST. GEORGE.—The work of cleaning up the St. George in preparation for its inspection by Mr. Schofield, who has a hand on it, is about done. It has been a long and difficult task, and its end will not increase the sorrow of any one. It will be examined immediately upon the completion of the work.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—Following is a summary of last week's operations on the Comstock mines from additional official reports:

In the Consolidated California & Virginia mine, on the 1650 level, the drift running north from the end of the crosscut run east from the drift run north from the east crosscut No. 1 from the north drift from the winze—down 52 feet—has been extended during the week 13 feet; total length 50 feet, continuing in porphyry, clay and quartz of low assay value. Have extracted from the workings in the vicinity of the winze—down 20 feet—17 tons of ore assaying \$51.40 per ton. Are doing some necessary repair work in the main south drift and openings therefrom on the 1600 level. 1000 level—the Rule drift—The upraise from this drift, started at a point 353 feet south of the shaft station, has been carried up during the week 26 feet; total height 66 feet, continuing in porphyry, clay and quartz of low assay value. East crosscut No. 3, started 20 feet south from the upraise, has been advanced ten feet in a quartz and porphyry formation of nominal value. East crosscut No. 2, started from the drift at a point 527 feet from the shaft station, has been extended 25 feet; total length, 85 feet; face in porphyry, clay and quartz of low assay value.

In the Ophir mine, on the 1465 level, the west crosscut on the north drift is in 48 feet, and continues in porphyry and clay seams. An advance of 38 feet has been made during the week in reopening and repairing the old Central tunnel, making the total length in a westerly direction 974 feet. From this point they have reopened and repaired in a northerly course 58 feet. Have continued (jointly with the Mexican Company) the work of making repairs to the main shaft. On the 1465 level of the Mexican mine and upraise, near the mouth of the west crosscut from the south drift, from the upraise 45 feet above the sill floor of this level, is up 40 feet. The top is in porphyry showing lines of quartz. On the 900 level of the Union shaft and Sierra Nevada joint east crosscut near the north line of the Union mine, started from joint north drift, which was run from the joint west drift at a point 1520 feet west of shaft, has been extended during the week 14 feet; total length, 170 feet; face in clay and porphyry, from which there is a small flow of water. In the Andes mine, on the 420 level, crosscut No. 3 is in 107 feet; formation clay and quartz.

In the Best & Belcher mine, on the 900 level, the east crosscut on the north boundary has been advanced 18 feet, passing through hard porphyry; total length, 431 feet. In the Hale & Norcross mine, on the 900 level, they have finished cleaning out and repairing the main south drift on this level, and resumed work in the face of same. Advanced this drift during the week 6 feet; total length, 147 feet; face in porphyry. 1100 level—Repairs to the main south drift on this level have been completed, and have resumed work in the face. This drift was extended 6 feet the past week, making its entire length 142 feet; face in porphyry. In the Kenton Con. mine, on the 1100 level, they have made the air connection with the 1035. Have started to follow southward the ore streak encountered in the raise. On the 1200 level the joint lateral drift with the Yellow Jacket in the west ledge is out 22 feet; face in gold ore of milling grade.

Potosi.—The south drift on the 450 level has been advanced 24 feet; total length, 252 feet. The drift is following a streak of ore 12 inches wide of good quality. The raise from the 450 level is up 32 feet; top in clay and low-grade quartz.

Chollar.—The north drift, 100 level, is now out 60 feet; the face is in clay and low-grade quartz. On the 100 level, 300 feet south of north line, have started a drift west, which is out 18 feet; face in porphyry.

Sierra Nevada.—The south lateral drift from the intermediate tunnel has been advanced 21 feet; total length, 515 feet; face in porphyry. The joint east crosscut near north line, from the north drift 1520 feet west of the shaft, 900 level, has been advanced 14 feet; total length, 170 feet; face in clay and porphyry, from which there is a small flow of water.

Union Shaft.—The joint east crosscut near north line, from the joint north drift 1520 feet west of shaft, 900 level, has been advanced 14 feet; total length, 170 feet; face in clay and porphyry, from which there is a small flow of water.

Ward.—The west drift from the station, 820 level, Ward shaft, is out 650 feet from the shaft; face in porphyry.

Bullion.—The west drift from the station, 820 level, Ward shaft, is out 660 feet from the shaft; face in porphyry.

Alpha.—Have been engaged in retimbering

the station at the 122 level and the shaft below that point.

Jumbo District.

DEVELOPMENT TO BE PUSHED.—*Territorial Enterprise*, March 24: The increasing demand for gold-bearing quartz veins has spurred on the lagging energies of owners of lode-titles in Jumbo district, and the work of development will be vigorously prosecuted there this year.

The Wild Goose, owned by J. C. Dunlop, has been a steady bullion producer since last summer, and there are now about 100 tons of ore on the mine dump ready for milling that shows an average value of \$20 per ton in gold. There is far higher grade ore in the mine, but the finest quartz is secured.

The ledge in the Wild Goose shows a width of 30 feet of vein matter, but only a part of it is pay. The walls are slate and syenite, and at the water level, 165 feet below the surface, the ledge shows stronger than at any other point. The water is not of great volume, but the cost of setting up and operating a pumping plant to follow the ledge below the water level would involve a greater outlay than the owner cares to invest at present, as the ore resources above the water level are ample to keep the force of three men employed for several months. Heretofore, Mr. Dunlop has had the ore from the Wild Goose crushed in custom mills, but hereafter he will handle it in his own mill adjacent to the mine. The mill has five stamps and can be operated by water power six months out of the twelve.

Captain Berry is extracting some high-grade ore from a vein cut in a tunnel which he has been driving to drain his property, and is now operating through a shaft. The ore saved is said to show an average of \$100 a ton in gold, and is sacked ready for shipment to one of the canyon mills.

C. S. Coffin is going out a little ore from the Pandora which has produced a larger amount of gold bullion than any other location in the district. Work on the Blizzard and all of the principal locations in Jumbo will be resumed next month. The district is conceded to be one of the best fields in the State for prospectors in search of gold-bearing quartz veins, and from present indications there will be more men working there this year than at any time since its discovery.

ARIZONA.

AN OLD MINE FOUND.—The old mine found near Cibola creek, Gila county, by young Edwards and others, says the *Arizona Gazette*, is turning out to be a magnificent property. It has for years been known that somewhere in that vicinity there was an old mine that had been worked by white men to great profit, but until lately its location had not been found. It is not in the canyon of Cibola, where so long it has been sought, but is on the high plain above, about a mile and a half west of Cibola creek and less than that distance north of Salt river. The dump is of large proportions, and the workings were evidently of considerable extent; how deep it cannot be ascertained, for the Indians, as usual with them, had filled up the shaft nearly to the surface. The company working the mine have started a shaft at another point and will tap the ore body below the old workings. The ore on the surface assays about \$35 a ton in free gold. Near the old works is still standing an adobe and stone cabin wherein the white miners of long ago had their residence, and whence they were driven to their death, no doubt, by the terrible Apaches. The mine is but a short distance outside of the reservation line, in a country that is the wildest on God's footstool. Undoubtedly it is rich in precious metals, yet only a small portion of it has been well explored, and in all Arizona it is least known.

THE VEKOL CLOSES DOWN.—*Tombstone Prospector*: Owing to the low price of silver another silver mine has been closed down. This time it is the Vekol of Pinal county. The Pioneer district in Gila county, which has made many chlorides independent for years, has also been totally abandoned.

OVER THEIR NEW ROAD.—*Prospector*: The Copper Queen Co. is piling up its bullion at Bisbee until its new road is constructed or the N. M. & A. makes a better rate. The *Prospector* is informed that the receivers recently appointed for the Santa Fe system are the cause of the trouble between the railroad company and the Copper Queen Co. over rates on bullion shipments.

LOWER CALIFORNIA.

COPPER MINE TO BE OPENED.—A San Diego dispatch, March 23, says: It will not be long until the real extent and worth of the San Fernando copper mine, below San Quintin, Lower California, becomes known. For 15 years this property has lain idle, with just enough water and debris in the shaft to prevent an inspection by intending purchasers without great expenditure of money.

Now, however, through the energy of Prof. E. C. Anthony and his son, a syndicate of Denver capitalists has secured a working bond on the mine, and will attempt its development. The syndicate is represented by General E. C. Humphrey, who has been in this city for some days fitting out an expedition to go down to San Fernando, and, accompanied by Fred Anthony and two mining engineers General Humphrey will leave San Diego to-morrow with an outfit. About 40 tons of supplies will be taken to Escondido on the Pacheco, and from there shipped to San Carlos landing.

It is the opinion of old settlers who are familiar with the property that the mine will develop into one of the best copper deposits on the coast.

OREGON.

GOON REPORTS.—*Baker City Democrat*: The news received regarding the Bonanza and Pyx mines in Robinsonville district is most flattering. A fine body of ore has been opened in the

lower level of the Bonanza and the *Democrat's* informant states that the mine is looking better than ever. "It is a great mine," said he, "and the showing of ore is something grand."

At the Pyx mine a millsite has been graded and lumber is now being delivered on the ground. Very rich ore is being taken out of the Pyx and the ore body is extensive. As soon as the mill is ready for operation there will be no end of ore for reduction.

NEW COAL FIELDS.—*Baker City Democrat*: Mr. S. Grier yesterday called at the *Democrat's* editorial rooms and laid on our table some fine coal specimens, which were sent to him by his sister, Mrs. M. E. Carroll, of Bridge creek, Crook county. Several discoveries have been made in that section and the lodes are showing up in fine shape. The specimens received were taken from a three-foot vein at a depth of 50 feet. Mrs. Carroll writes that the quality of coal improves with depth.

RICH PLACER.—*Bogue River Courier*: Sam Axtell was up from Gelice creek this week. He and Gene Merrill bought a half interest in 40 acres of good mining ground for \$500 and are busy ground-slucing with rich results. The bedrock has not yet been reached, but a phial filled with coarse gold shows that the bank carries colors clear down.

NEW MEXICO.

INSPECTOR'S REPORT.—A dispatch from Washington says: John C. Spears, United States Mine Inspector for the Territory of New Mexico, has submitted his monthly report to the Secretary of the Interior. He reports having inspected the Brown mine, in Chirillos, and found that the laws to ventilation had been complied with, excepting in the case of the main slope. The defect is to be remedied. The White Ash mine was found to be generating fire damp at the left entries. The report is accompanied with the verdict of the Coroner's jury rendered at the inquest on the death of Peter Fochetti, who was killed in the Waldo mine on January 30th. The verdict was that Fochetti came to his death from a premature discharge of shot, believed to have been fired by himself.

The explosion of fire damp in the Blossburg mine, which resulted in the death of four miners and the injury of several, is treated exhaustively in the report. Inspector Spears states that he called the attention of the pit boss and superintendent to the bad condition of the mine. He is of the opinion that the explosion could have been prevented by the exercise of due care after the discovery of fire damp in dangerous quantities. The company operating this mine has been given twenty days in which to comply with the law of ventilation.

UTAH.

MERCUR DISTRICT.—"It will, in time, be the greatest gold camp in America, if not in the world." This is what Tim Driscoll, the well-known miner, said of the Mercur district. Mr. Driscoll had just returned from Mercur, and has thoroughly investigated the wonderful gold fields. He further said to the *Salt Lake Tribune* reporter: "It is the most peculiar camp in the world. Scarcely one practical miner out of a thousand would consider the rock of any value as gold-bearing rock."

"The dirt or rock may be pounded and panned without getting a color of gold, but after witnessing the process of extracting the gold and seeing the water that comes out as clear as spring water and examining the zinc shavings after the water or cyanide solution passes through them, and finding them coated with gold, you would not only be staggered but also firmly convinced that there is also a new feature and a new field in gold mining; also that the two recent rich strikes, one at the Sunshine, three miles west of the Mercur, and the other at the property owned by the Electric Light Company of this city, three miles south of the Sunshine, goes to prove that there is an extensive and inexhaustible field of the same quality of ore extending over a broad area of country."

WASHINGTON.

RICH PLACER.—Some wonderfully rich placer diggings are being worked in the upper Big Bend of the Columbia. O. B. Williams and J. W. McCreary arrived at Revelstoke on snowshoes from French creek last Saturday, making the 60 odd miles in three days. They have taken out considerably over \$6000 from the Consolation mine, the result of four men's work since December 1st. The pay streak is 25 feet wide, and with three shifts can easily work between 30 and 40 men. By actual test the gravel averages clean through the pay streak \$15 a day to the man, and there are some 3500 feet of the mine yet untouched. About a quarter of a mile below the Consolation the Vandall people have struck a bonanza. They have a tunnel into the bench, and have struck the rim rock of an old channel. How much they have taken out so far is unknown to Messrs. Williams and McCreary. Williams went into the tunnel the day they left, and the owners, as an illustration of the mine's wealth, cleaned up about \$100 off the bedrock while Williams was standing in the drift.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

—It is again reported that a contract has been signed for the construction of a railroad from Portland to Astoria, Or.

Industrial Education.

James Spiers, President Fulton Engineering and Ship-Building Works, in *Evening Bulletin*.

Noticing in a recent issue of the *Bulletin* an editorial on the Wilmerding, Cogswell and Lick schools, for the purpose of educating our youths and preparing them for industrial pursuits, prompts me to write to you on the subject, having given it considerable thought during my experience as a mechanic and knowing the difficulties experienced by boys in learning a trade and combining with it that education which enables them to reach the highest positions.

The object of all these gentlemen was evidently the same; that is (taking into consideration their condition), to teach youths how best to earn a living. Such institutes should take our youths just as they come from the grammar schools and give them such a course of instruction that at the end of four years they are prepared to earn their living.

This end cannot be accomplished by the courses generally pursued in similar institutions, as the students coming from such, going into our workshops, are on an average in no better condition to earn a living than apprentices who have been six months at the trade. They are better versed in the sciences than the six-months apprentice, but no better in their ability for practical work.

The ability by educated experience to do practical work is a more potent factor in earning a living than the possession of scientific knowledge, however desirable it may be. A knowledge of the higher branches of mathematics and physics is exercised by but a very small percentage of our artisans, and, therefore, the aim ought to be to reach the masses, while at the same time paving the way for those who will reach out and go higher. To do the greatest amount of good, education in practical work should be followed out very much in the same way as in our regular workshops.

Institutes of this kind, so far, have been organized by attaching workshops to the college. In such workshops the work carried on is experimental and does not make workmen. These workshops are carried on more for the purpose of making experiments in testing material and making fancy articles, and always seem to me to be playing at work instead of doing work. What I think should be done is to build workshops and attach the classes to them. Organize them to do work similar to that of the regular business workshops of the country; to manufacture articles for sale, such as tools, engines, wood-working machinery and articles of common use, whatever the branch of industry may be, so that apprentices while learning are producing, and are at the same time acquiring those habits of industry which go to make the first-class workman. Such workshops should be so organized that the day would be divided in two, the first half being used for practical work, and the other half for study, the hours employed each day to be not less than five, which would at the end of four years enable a youth of ordinary intelligence to master the trade. Five hours each day exercised in practical working for four years, under instruction such as should be given, will be as valuable as nine hours in the ordinary shops. The opportunity given for scientific study in the afternoon will, during the four years, enable those students who will naturally forge ahead to reach as exalted positions as can be reached through any other channel.

In consideration of apprentices, while learning, being producers, I think they ought to be paid during the third and fourth years of their apprenticeship.

The articles manufactured, being of common use, will be sold from time to time, and the proceeds apply in a great measure to the supporting of the institute.

During the first years of their instruction, with little experience, it will be necessary to introduce a few good workmen in addition to the foremen, and it may be necessary to have a few all the time, but by the time that the junior and senior years are reached the number of experienced workmen can be reduced, the juniors and seniors by that time being sufficiently experienced to take their places.

It is unnecessary to discuss all the details of such a plan in this letter, but it is a subject to which I have given considerable thought during my experience with workshops and apprentices. I do not write this for the purpose of showing that workshop education is more important than college education, but simply to show that in such a plan as Mr. Wilmerding's its purposes can best be carried out as I have outlined; the workshop coming first and the higher branches of education being second. For professional men, and men whose

lives are to be devoted to science, the practical education cuts but a small figure, and to them is of small importance. In all cases the education should be of such a nature as to best suit the class which it is intended to assist.

JAMES SPIERS.

Market Reports.

The Markets.

SAN FRANCISCO, March 29, 1894.

No new feature has developed in silver during the week, the range of quotations being singularly uniform. At this writing (Thursday) it is regarded as certain that the President will veto the Bland sealage bill, and there is no probability that it can be passed over his head. The effect of the veto on the market appears to have been fully discounted, as, indeed, have all other adverse influences. Talk of the rehabilitation of silver by European countries and by Mexico have been events of the week, but they have so far resulted in no definite move looking toward international bimetalism.

Lead.

The lead market has suddenly strengthened, due to the favorable action of the Senate committee on the tariff. The advance has been from .2 to .3 of a cent per pound, sufficient to encourage the miners very much. At this figure it will be possible for some large mines, now shut down, to operate without loss.

There is no change in copper.

New York Prices.

NEW YORK, March 29.—Following are the closing prices for the week:

	Silver in London, N. Y.	Copper.	Lead.	Tin.

Mining Share Market.

SAN FRANCISCO, March 29, 1894.

The Comstock market has been in a weak condition for the past week, and prices have almost uniformly declined. The best sustained and most active stock during last week was Potosi of the middle group, which had some lively fluctuations, mostly on a small scale. The official letter from the Potosi mine for the past week, a copy of which is published below, states that the south drift on the 450 level is following the ore streak encountered two weeks ago, and the ore in the face of the drift is 12 inches wide and of good quality. Private advices report that the ore assays from \$100 to \$200 per ton. This ore streak has been of varying width and has been followed by the drift for nearly 60 feet from the point where it was first found. In the opinion of people who are familiar with the Potosi mine it constitutes a very hopeful prospect, the best, perhaps, now visible in any of the Comstock mines.

Tuesday the difference between the price of Consolidated California and Virginia and Ophir, which has been narrowing for several weeks past, got down to ten cents for when Con. California sold at \$2.50 Ophir brought \$2.40. People who made bets a week ago that Ophir would sell higher than California were greatly elated.

Yesterday the Comstock market had a sharp decline at the opening. A combination of Board brokers who were among the thirteen who voted against the amendment to the Constitution permitting fluctuations of 1 cent in stocks selling below \$1, slaughtered stocks to prove, as one of them intimated, "that the rule was a bad one and should be repealed."

—Capitalists have a scheme to furnish electricity to Stockton for manufacturing purposes. It is proposed to generate the power in the Stanislaus river above Knight's Ferry.

—Most of the Mare Island shops are expecting a heavy reduction in force by April 1st. It is true that there is a big job on the Boston, but there is no money to carry on the work.

Coast Industrial Notes.

—Electric signals are being put up by the railroads at the street crossings in San Jose.

—After nine weeks of boring the Healdsburg Trust Company has struck water at a depth of 280 feet.

—A returned prospector from the Goler and Red Rock camps tells a new story. He says there is little gold in that section. He declares the reported finds at Black Mountain to be "fakes."

—A company has been formed at Riverside to erect a 400-room hotel. The capital stock of the corporation is \$450,000. The building will cost \$200,000, and work will be commenced soon.

—The Portland City Water Committee has asked for proposals for the construction of four reservoirs, to cost over \$500,000. It has ordered the sale of \$1,500,000 bonds to carry on the work.

—Indian creek dam, Idaho, the hurstling of which caused such a havoc recently, was not destroyed. The damage can be repaired for a few thousand dollars. The water was more than twenty feet from the top when the accident came.

—The rails of the Southern Pacific Coast line are now laid to near San Luis Obispo. In two weeks the bridge will be in place. Indications point to the continuance of the work south. Strangers are flocking to that section, spying out the country.

—Hon. W. J. Mills of Pocatello, Idaho, read a paper at a session of the State Irrigation Committee in which he stated that the government, by expending \$10,000,000 could reclaim Snake river valley lands and provide homes for 250,000 people.

—For some months past a party of surveyors has been at work surveying the channel of the San Gabriel river, from its mouth at the ocean to the San Gabriel canyon. It is stated that the intention of the Board of Supervisors is to give employment to the idle men of the county at a nominal sum.

—Representative Wilson of Washington is making inquiries as to the contract which the Treasury Department is said to have made with the British Coal Company for supplying \$100,000 worth of coal to United States vessels which will patrol Behring sea. Wilson regards the contract as a discrimination favorable to British interests. He says it is especially objectionable in view of America's contention with Great Britain over the Behring sea. Wilson has unofficial information that the contract was made with the Comox mines on Vancouver island, although there are abundant coal supplies in the Puget sound country.

—A census bulletin shows that there are in California 7923 manufacturing establishments. The aggregate capital invested is \$146,797,162, live assets \$66,792,498, averaging number of employees 83,642, total wages \$1,538,780. Operatives, skilled and unskilled—Males above 16 years 50,569, wages \$32,913,974; females above 15 years 69,785, wages \$2,130,192; children 1513, wages \$216,478; piece-workers—Males above 16 years 8496, wages \$4,674,798; females above 15 years 4806, wages \$1,158,850; children 344, wages \$33,626. Cost of material used, \$120,241,025; value of products, including receipts from custom work and repairing, \$213,404,091.

—An important contract was recently entered into by the San Carlos Coal Company of Pittsburg and the Southern Pacific Railroad Company, by the terms of which the former, owning extensive coal lands in Texas, is to furnish the railway company with 115,000 tons annually, 315 tons per day. The transaction also embraces the building of a railroad twenty-six miles in length, at a cost of \$300,000. The property on which the company is now operating consists of 1280 acres of land in Presidio county, Tex., acquired by purchase in fee from the State of Texas, all of which is underlaid with coal, and 55,120 acres held by the company under a lease from private owners in fee for the term of thirty years from May 16, 1892. In addition to this, the company has a lease for twenty-five years on 2,000,000 acres of land situate in the district of Iturbide, Republic of Mexico, on the Rio Grande. Prospecting has been carried on in the Mexican property sufficiently to determine that it contains a bed of coal about fifty miles in length, and from ten to fifteen miles in width. The vein is forty-one inches thick, and of good quality and semi-bituminous in character. It is said that at the mines now open the San Carlos Company can get \$2.50 per ton for coal on the car, and the profit will be about \$1 per ton.

—An important case has just been decided by the Supreme Court of this State involving the title to the Chile Bar Slate Quarry near Placerville under the title of

The People, respondent, vs. W. O. Thomas, appellant, an appeal having been taken from an order refusing to set aside and vacate a judgment. The State sold the west half of section 36 as school land to Thomas in 1875, and in 1880, as he failed to make the requisite payments, the certificate was foreclosed and judgment was entered against him. In 1875, Thomas sold the land to the El Dorado Slate Company, but the conveyance was not recorded till August, 1892, nor was the Register of the State Land Office notified. In January, 1887, the State sold a part of the same land to Leonard Reeg, who sold it in 1888 to Mothersole & Perine, who have expended thousands of dollars on it in quarrying, not knowing of the other transactions and being innocent purchasers, while at the same time the El Dorado Slate Co. knew of their purchase and improvements. In January, 1893, the case was tried in the Superior Court before Judge Arnot, an effort being made to set aside the judgment against Thomas on the land. There were some minor irregularities affecting the cancelling of the certificate to Thomas, but the equities were so strongly in favor of the present owners of the land that Judge Arnot refused to set aside the judgment, and the title to the quarry now held by Mothersole & Perine is confirmed.

516,897.—HOOR—C. W. McMillan, Harleton, Cal.	516,743.—REVERSIBLE PLOW—W. W. Miller, Noyo, Cal.
516,727.—BALNO PRESS FEEDER—D. J. Overholzer, Spadra, Cal.	516,744.—CURLING IRON—T. F. Payne, Olympia, Wash.
516,911.—WATER MOTOR—W. H. Rucker, Hillsborough, Ugn.	516,670.—KNOB—Jacob Weather, Aberdeen, Wash.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SEPARATOR.—Robt. W. Jessup, Los Angeles, assignor of one-half to Fairfax H. Wheeler, Santa Barbara, Cal. No. 516,440. Dated March 13, 1894. The object of this machine is to separate particles according to their difference in length and, incidentally, according to other differences which would, with certain particles, enable them to readily pass through a hole and with others would retard or prevent them from so doing. Though the machine is applicable to the separation of various materials,

it is to be specially applied to the separation of oats and barley from wheat. The device consists of a perforated disk rotating in a vertical plane or substantially such a plane, a feed device applied to and adapted to maintain a layer of material against the uprising side of said disk, and a suitable backing applied to the reverse side of the disk on its uprising semi-area. The wheat will enter and pass through the holes of the disk, but the barley and oats will not.

BALING PRESS FEEDER.—No. 516,727. Dated March 20, 1894. David J. Overholzer, Spadra, Cal. This invention relates to an apparatus which is designed to feed hay or other material to a horizontal press in which the follower is adapted to reciprocate so as to compress the material into a bale. It consists of a hopper with swinging plates and arms and connections by which they are actuated so that the feed board forms one side of the hopper when open, and is actuated by the mechanism to force the charge into the press in front of the follower.

MOUTH-PIECE FOR MUSICAL WIND INSTRUMENTS.—No. 516,938. Joseph C. Ingram, San Francisco. The object of this invention is to provide a mouth-piece for wind instruments, having such a construction as will assist to hold the lips in proper position to produce the requisite tone. In the ordinary mouth-piece the performer must depend upon the muscular contraction of the lips and the pressure of the mouth-piece against them to hold them in proper position to produce the tone, and after a time the lips are apt to slip upon the mouth-piece and spoil the tone. In this invention a raised rim or fillet is formed upon the flat surface of the mouth-piece which serves the purpose.

TIMBER PRESERVING APPARATUS.—No. 516,730. Wm. G. Curtis and John D. Isaacs, San Francisco.

This invention provides a portable plant which is especially serviceable for use upon lines of railway. It consists of retort sections, each mounted upon railway trucks so as to be moved independently from place to place, and means for uniting the sections into lengths sufficient to hold the timber to be treated up to any desired length. Upon another car or cars are mounted a steam boiler, tanks containing the preservative compound with pumps and means for applying the compound after the moisture has first been driven from the timber. Within the retorts are cradles mounted upon trucks adapted to properly contain the timber and steam pipes with manifolds or steam chests and adjusting devices to compensate for expansion and contraction.

REVERSIBLE PLOW.—Wm. W. Miller of Noyo, Cal. No. 516,743. Dated March 20, 1894. This plow has a double mold board mounted upon a horizontal axis, adapting it to be turned through an arc in a vertical plane to fit a stationary land-side at either limit of its movement. The plow bottom is laterally concaved, and it has duplicate opposing share extremities. The object in view is to provide a plow not only adapted for use on side hills, but equally applicable for use on level ground, it being capable of perfect use in either or both situations.

Assessment Notices.

SUPERIOR MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Placerville, El Dorado County, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 13th day of March, 1894, an assessment (No. 1) of Twenty Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, Room 17, 313 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 14th day of May, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors.

R. W. HEATH, Secretary.

Office, 316 Pine St., Room 17, San Francisco, California.

GEO. E. BELMOR,

OF THE BELMOR BOILER WORKS,

Has Removed from 210 Mission St. to 52, 54 and 56 Bluxome St., bet. 4th and 5th.

(To the old H. W. Rice Machine Works.)

FOR BOILERS, DREDGING BUCKETS AND SHEET IRON WORK, CORRESPOND.

PORTLAND MINING BUREAU.

Mining Properties in OREGON, WASHINGTON and IDAHO Listed For Sale.

ORES EXHIBITED AND ASSAYS MADE.

W. C. COWWILL, Secretary, Room 9, Chamber of Commerce Building, PORTLAND, OR, P. O. Box 350.

UNION IRON WORKS,

CORNER FIRST AND MISSION STS., SAN FRANCISCO, CAL.

MANUFACTURERS OF

MINING AND MILLING MACHINERY,

Automatic Cut-Off Engines, High-Speed Engines, Hoisting Engines, Quartz Mills,
Manty Chili Mills, Rolls and Concentrating Machinery, Dodd Sigmoidal Water Wheel,
PUMPS (Cornish and Other), Copper and Lead Furnaces, All Classes of Marine Work,
SHIP BUILDERS, BUILDERS OF U. S. WAR SHIPS. HYDRAULIC LIFT DOCK.

STOCK OF

MINING MACHINERY

SOLD AT LOW PRICES.

21 & 23 FREMONT ST., S. F.

FULTON ENGINEERING AND SHIP-BUILDING WORKS.

Successors to FULTON IRON WORKS (Hinckley, Spliers & Hayes), and F. A. HUNTINGTON.

OFFICE AND BRANCH WORKS: 213 FIRST STREET. - - - MAIN WORKS: HARBOR VIEW, SAN FRANCISCO, CAL.

MINING AND MILLING MACHINERY.

ADAPTED TO EVERY DESCRIPTION OF MINING AND MILLING.

Manufacturers of the TUSTIN PULVERIZER: Adapted to Wet or Dry Crushing.

Also the well-known HUNTINGTON CENTRIFUGAL ROLLER QUARTZ MILL.

Special Descriptive Circulars of these Mills sent on application.

Specialties Manufactured by us:—"HUNTINGTON" BLAKE ROCK BREAKER; "FULTON" BLAKE
ROCK BREAKER; FRUE VANNERS; "BOSS" CONTINUOUS SYSTEM.
Manufacturers of all kinds of ELECTRIC LIGHT AND ELECTRIC R.R. AND CABLE R.R. PLANTS.
STEAM ENGINES—Plain Slide Valve, Corliss High Pressure, Corliss Compound Condensing & Non-Condensing.
Agents and Manufacturers of the De La VERGNE REFRIGERATING MACHINES, FILTERS OF
THE NEW YORK FILTER COMPANY.

Sole Agents for THE DEANE STEAM PUMP, ARMINGTON & SIMS ENGINES, LEFFEL
WATER WHEELS.

TUSTIN'S PULVERIZER—Works Ore Wet or Dry.

CENTRIFUGAL ROLLER QUARTZ MILL.

THE PELTON WATER WHEEL!

EMBRACING IN ITS VARIATIONS OF CONSTRUCTION AND APPLICATION

THE PELTON SYSTEM OF POWER.

The most simple and efficient water power appliance for mining, electric or other service. Full and reliable information given regarding any proposed application upon receipt of the necessary data.

THE PELTON WATER WHEEL CO., 121 Main St., San Francisco, Cal.

THE GATES ORE AND ROCK CRUSHER.

Superior to all others for either mining or road work. Send for circular.

THE PELTON WATER WHEEL CO., 121 Main St., San Francisco, Cal., General Western Agents.

NOTICE TO GOLD MINERS! SILVER-PLATED AMALGAMATED PLATES For SAVING GOLD!

IN QUARTZ, GRAVEL, OR PLACER MINES.

MANY BEST SOFT LAKE SUPERIOR COPPER.

AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved the best in weight of Silver and durability. Old
Mining Plates Replated, Bought, or Gold Separated. THOUSANDS OF ORDERS FILLED.

SAN FRANCISCO NOVELTY AND PLATING WORKS (INCORPORATED),

SEND FOR CIRCULARS.

Two Kinds of Stamp Mills.

Mining literature has recently found considerable additions in a discussion as to the relative merits of Colorado stamp mills and California stamp mills. The Press has given space to the discussion, which has been both interesting and profitable; and the conclusion reached seems to have been that the California mill is best for California and that the Colorado mill is doubtless all right for Colorado. The essential difference between the two mills is that in one there is a fast and low drop, in the other a high and slow drop. In other words, the Colorado stamps

concentrator used is what is known as the "Gilpin county" bumping tables. Even the rock-breakers and the automatic feeders are different. Everything is different, and yet we are told that at one 94 per cent of the gold is saved with the concentrator; in the other, 89 per cent without. When the concentrator is running in the latter, the percentage, it is thought, will be brought up to 95.

This experience seems to prove that, in one instance at least, there is no room for controversy as to the values of the mills. Both are good.

Two hydraulic mining companies which had projected

The Pelton Water Wheel.

The illustration here presented shows a Pelton wheel equipment, mounted on a cast iron base with iron housing, including a differential governor, operated by a constant speed motor. The hearings are fitted with ring-oiling boxes, and the work throughout fully up to the highest standard for this or any other class of machinery. While these wheels are usually mounted on timber frames, and answer well in this way for all ordinary purposes, the design here presented is very desirable for running electric plants, and other installations of a permanent character.

STANDARD WATER WHEEL, FROM 50 TO 500 H. P.

drop (roughly speaking) twice as far and half as fast as the California.

In this connection, the experience of the two ten-stamp mills at Vanderhilt, in this State, is both curious and interesting. These mills, it is well known, have just been placed in operation. It had been predicted that the mills would not be successful, inasmuch as the ore is variable and of an unusual character. The gangue is quartz, honeycombed at the surface from the oxidation of sulphurets it originally contained, small disseminated crystals of which (iron, lead and copper) begin to show in the rock from the deepest part of the workings. Some of the rock contains a high percentage of lead in the form of galena and carbonate, but it occurs in hunches and is not evenly distributed through the rock. The Campbell mine has a Fraser & Chalmers mill, with 750-pound stamps, that drop seven inches 90 times per minute, and it has an Evans concentrator. The Vanderbilt Mining and Milling Company has a "Gilpin county" mill, with 650-pound stamps that drop 16 inches 30 times per minute, and the

and were carrying out large works in Plumas county, and which had obtained the necessary permission from the Debris Commission, have encountered an unexpected obstacle. Five farmers owning land adjoining a creek, within the tributaries of which it is proposed to deposit debris, have filed formal protest with the Debris Commission, and have likewise served notices upon the companies that they will take legal steps, if necessary, to prevent mining. The folly of all this is unspeakable. The riparian owners have no ground of complaint, or even apprehension of injury. There are four substantial dams in the stream, the plans of which have been pronounced adequate and secure by the Debris Commission, who are competent judges. It appears, further, that two of these farmers had already granted rights of way through their premises, and a third has since withdrawn his name from the remonstrance, leaving but two in a consistent position for objection. The companies state that they will pay "blood money" to no one. Perhaps, when the position of the companies is better understood, the objections will vanish.

The Pelton wheel—it is well known—is now almost exclusively used for every variety of service where the conditions permit as to head. It is especially adapted to running electrical machinery, from the perfect regulation afforded as also from the facility with which provision can be made for all the varying conditions of service as to speed, power, etc.

A wheel plant similar to that here shown has recently been furnished the Amador Light & Power Company at Sutter Creek, and another is under construction for the State Trade School at Ione.

COLONEL GEORGE H. MENDELL, Corps of Engineers; Lieutenant-Colonel William H. H. Benyard, Corps of Engineers, and Major William H. Heuer, Corps of Engineers, have been reappointed members of the California Debris Commission.

REPRESENTATIVE COFFEEN has introduced in Congress a bill for the free and unlimited coinage of silver dollars of 412½ grains.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Standard Water Wheel, From 50 to 500 H. P., 209.
EDITORIALS.—Two Kinds of Stamp Mills; The Pelton Water Wheel; Miscellaneous, 209. California Mines at the Midwinter Fair; The Spy System; Ownership of Mines; Miscellaneous, 210.
MISCELLANEOUS.—Slickens: Caminetti a Friend of Silver, 211. The Cour d'Alene Snowdrifts; A New Chlorination Process; Foundry Notes; The Coxy Movement; Fish Display at the Fair; The Irrigation Movement, 212. Apex and Side Line; Silver-Lead Smelting Practice, 213. American Improvements and Inventions; Gold Mining in the Colony of Victoria, 214. Auriferous Beeches of New South Wales; The Hurleton District, Butte County; Miscellaneous, 215. Hunting Lost Mines; Why Big Salaries Are Paid, 218.
SCIENTIFIC PROGRESS.—The Seven Images of the Human Eye; The Influence of the Mind Upon the Body; Transparency of the Ether, 216.
MECHANICAL PROGRESS.—Superheated Steam in Small Motors; Improved Steam Pipes; Large Pulleys; Manufacture of Bronze Powder; Cutting Mica, 217.
USEFUL INFORMATION.—Famous Meteoric Stones; Florida Ants; Boiling Water Not Always Hot; Snells Live Indefinitely; How Old Is the Human Race? 218.
ELECTRICITY.—To Utilize the Bosphorus; Winding and Setting Tower Clocks; An Inexpensive Electrical Machine; Making Ozone; The Poor Man's Light, 218.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 221-2.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 223.

It is a curious fact that almost the only present disturbances in the labor world should be in the mining regions; and it is remarkable, also, that the feeling in each of the strikes should be so intensified as to reach the point of personal violence. At Cripple Creek, at Kreles, Colgate and Lehigh (Indian Territory), and in the Pennsylvania coke regions, there has been much trouble, and the end is not yet.

THE Boston & Montana Mining Company seems to have had a prosperous year during 1892, notwithstanding the great depression in copper. The directors say their works have more than met expectations. Especially is this the case with regard to the electrolytic plant, the production of which is a great deal larger than it was supposed to be capable of, and they still feel that they have not yet reached the limit of its productiveness, nor the still further reduction of cost of operation in all departments of the whole plant. The books show a balance, December 31, 1893, of \$350,000.

THE Cripple Creek mining troubles seem as far from settlement as ever, and it is doubtful when this noted camp will be able to resume operations. Since the Cripple Creek miners rejected a recent compromise, the mine-owners declare that they will make no further effort to meet unions or committees, but will operate their properties with non-union men or not at all. The situation is indeed unfortunate. So many compromises have been proposed that it is remarkable no basis has been reached upon which there can be an understanding. The mine-owners and the miners have both receded from their original demands, but they are no closer together. Just how near they were to agreement will be seen when it is stated that the mine-owners offered \$2.62½ for seven and one-half hours' actual work; the miners wanted \$2.75 for the same time.

THE veto of the seigniorage bill is not to be regarded as an unmixed calamity. It was at best only a makeshift, designed to relieve the present pressure on silver, and to open the way for better prices. But it committed the Government to no definite policy, and the situation would have been no better one or two years in future than now. What is needed is a change in the fundamental policy of the Government. The veto, we think, emphasizes the position of the Administration against silver and serves notice upon the world at large that any sort of relief from that source is not to be hoped for. It is well enough to know this, even if it costs something; and the knowledge will undoubtedly increase the activity of the friends of bimetallism and strengthen their hands. It is necessary sometimes to cut off a limb to save a life, and the severe object-lesson the evils of restricted circulation and monetary disorder, which has been afforded the world by the recent hard times, are not without their benefits.

Ownership of Mines.

Mr. Albert Williams, Jr., in the *Engineering Magazine* of April, makes a recent article in the PRESS the basis of a discussion of the patent system of ownership of mining claims. The objects of the present law he very clearly states in the following:

It has been the aim of the law-makers in the United States and the Spanish-American countries to accomplish two results—to encourage the active development of the mineral resources and at the same time to secure owners in their holding. To gain these two things laws have been framed whose provisions are in a measure antagonistic. First, to compel the claims to be worked, there is the assessment-work plan (temporarily suspended in the United States), which requires the owner to do a certain amount of work each year upon his claim, the penalty being forfeiture of title and liability to having the claim "jumped" by any one who considers it worth taking up, and, in the early rough-and-tumble days, who was strong enough to hold possession. Then there is the patent system, intended to firmly secure title to owners who have gone through certain forms of locating, having official surveys made by government deputy surveyors, advertising intention, paying certain fees and doing certain work; after which, a patent having been issued through the land office, the theory is that the title is safe in perpetuity.

It cannot be disputed that both systems have their weak points. It is well known in the West that the assessment-work requirement for unpatented claims is subject to great abuses. In the nature of things, what constitutes \$100 worth of work on claims, all of which present a great variety of conditions, it is not possible to determine definitely; and consequently it is practically not determined at all, but is a matter left largely, if not wholly, to the inclination and conscience of the miner, or to his apprehension that his claim will be "jumped" if a showing of work is not made. All are agreed that the present law is inefficient and unsatisfactory, but all are not agreed as to what is the proper remedy. Indeed, there appears to be no general disposition among mining men to secure any kind of improvement, but to let well enough (or bad enough) alone. It is likely that if some plan, proposing a change and having features which appeal strongly to the fairness and justice of miners, were proposed, it would be seriously advocated by them, and might lead to reform.

The patent system is not subject to the same criticism, though it has its objectionable points, some of them growing out of the assessment plan. The essential difficulty is to devise a system of ownership which shall secure absolute title to property that is in one sense invisible, intangible, and not absolutely definable by metes and bounds; in other words, to property *out of sight*. We are not sure that the trouble with present titles lies with the patent system; it is with the nature of the property. The trouble is, and always will be, that the nature, extent and direction of quartz ledges are not ascertainable at the time it is first desired to secure absolute possession; and, therefore, under any system, conflicts, disputes and suits at law are bound to ensue. It may well be admitted that the present mining laws are intricate, burdensome, vexatious and contradictory, and are in need of material amendment; worse yet, the present laws are not interpreted in their proper spirit by at least one important branch of the government service, and there is sad need of a new code which will not only define the rights of one miner as against another, but as against all the world. But there is danger that any proposition which involves a change of the principle of ownership will be retroactive, and should not be undertaken without serious consideration. Under present conditions it might do more harm than good.

The Spy System.

The Debris Commission is awaiting for instructions from Washington as to its powers for punishment of offenders under the Caminetti act. It seems to have been clearly intended by the framers of the law that the entire control of hydraulic mining should be vested in the Commission, as witness the following sentence from section 19:

Said Commission shall take necessary steps to enforce its orders in case of the neglect, failure or refusal of such owner or owners to comply therewith, or in the event of any person or persons, company or corporation, working by said process in said territory contrary to law.

There ought to be no question what the above means; but it is very natural, under the circumstances, that the Commission should hesitate to undertake the duties and authority of police officers. It would involve the employment of an added force, which it has no funds to employ, even if it has the power, and it means an increase in the Commission's labor which it is not now able to perform.

There are doubtless other reasons why the Commission is reluctant to undertake the punishment of malefactors. For years the Anti-Debris Association has maintained a system of espionage over hydraulic mining that has brought discredit upon them. They hired spies and informers who, for hope of reward, patrolled the mining regions and endeavored to "catch in the act" any who were engaged in illegal mining. It is a singular fact that, despite the elaborate detective system of the anti-debris advocates, the total number of arrests during a long series

of years did not reach fifteen; but it was kept up all the same, at large expense. The Anti-Debris Association has by no means considered that it was pursuing its aims by the most laudable and desirable methods; but it has declared, substantially, that the end justified the means, and these means were all that were practicable. The spy system has been the direct source of very much of the hostile feeling that long existed between the farmers and miners. No wonder the Debris Commission is loath to engage in a work inaugurated and maintained under such auspices, and which is certain to engender more trouble in future if not dropped.

California Mines at the Midwinter Fair.

Placer County.—The exhibit of Placer county is distinctive. In its main features it is altogether different from other counties, and for that reason attracts at least as much attention as any other. Placer county is the home of drift mining. Within its borders this interesting branch of the industry has reached its highest and most extensive development; and it is here also that those intricate geologic problems which have confronted the engineer who has attempted to locate the lava-capped auriferous channels have been met and solved. Drift mining is *sui generis*. Its successful pursuit requires a peculiar experience, or, rather, an adaptation of general engineering and mining experience in a new direction. The pioneers in drift mining made Placer county the scene of their operations. The early miners soon discovered that the richest gold-bearing gravels lay immediately on the country rock and followed it into the mountain side. Being then unable to remove the great masses of barren earth and nearly barren gravel overlying, the rich gold-bearing portion of the latter was followed by tunnels, broken out by methods of underground mining, brought to the surface and there washed for gold. Subsequently it was discovered that auriferous gravels also underlay some of the gravels and volcanic wash. These deposits, being those exposed on the benches and slopes of the lava-capped mountains, were followed by tunnels and mined, and finally, inferentially, the existence of auriferous gravel under the lava, where there were no surface indications, was assumed, and tunnels were run into the side of the mountain to locate and mine it. As early as 1853 the mining of the deep-buried auriferous placers through tunnels, and in a manner analogous to coal mining, was commenced. This branch of gold mining soon became known as "drift mining," and was so distinguished from hydraulic, river or bar mining. No statistics have ever been kept showing the amount of gold obtained respectively from drift, hydraulic and surface mining, the latter including river beds, but Russell M. Dunn, M. E., an authority, considers it probable that, in the aggregate, from the discovery of gold to the present time, the yield from drift mining is close on to that from surface mining and somewhat in excess of that from hydraulic mining—an estimate that will surprise many who have not followed closely the history of the various branches of the industry in this State. In its early history drift mining was a succession of expensive failures and brilliant successes; now the chances of failure are reduced to a minimum, and it is possible to determine in advance, with reasonable certainty, the chances of opening up a pay channel in a given instance.

This introduction serves to indicate the essential feature of mining in Placer county; and it is to be expected that, in making an exhibit of its mineral resources, the drift mines would be given a conspicuous place. The purpose of the collectors of the exhibit has been well carried out. The display as a whole is unique, tasteful and instructive. The exhibit occupies a space about 17x21 feet, and at each end are placed prominently large square glass cases, containing characteristic gravel from the Sunny South (Hidden Treasure), Red Point, Mayflower and Doolittle mines, respectively. In the center is a pyramid of quartz from the working mines of the county, surmounting which is a fifth case, containing gravel from the Morning Star drift mine. Within the gravel is distributed quantities of drift gold, designed to illustrate the manner in which it occurs in the channels; and surrounding the base are collected quantities of howlers, petrifications, gravel and debris, showing the average composition of the channels, as well as the volcanic capping. It is interesting to note that the characteristic howlers from two mines are quartz, while those from two others are the plain striped. One oak petrification is worthy of note. It weighs about 20 pounds and has preserved the oak formation in an unusually perfect form. This petrification is said to be worth about \$200. It is from the Doolittle mine. One howler from Col. Doolittle's mine is covered with sulphurets.

Next in importance—and by many considered first in interest—is the fine collection of drift, quartz and placer gold shown in the cases in a prominent place. The specimens have been arranged with a view to catch the

casual glance, and they are indeed most beautiful. The rarest specimen is perhaps a fine piece of leaf gold from the cabinet of Mrs. M. H. Dodge, Forest Hill, worth \$100. Mrs. Dodge also shows a nugget worth \$180, the most valuable single piece in the collection. Two cases of great value are from the Hidden Treasure mine, showing drift gold, the largest piece of which is worth \$110. The Morning Star mine, owned by Hon. Jacob Neff, displays a fine variety of drift gold, collected in the significant form of a star. One case of specimens from the Drummond quartz mine is shown by Charles T. Reed. The specimens are fairly brilliant with leaf gold, the case being worth \$1000. The celebrated Mayflower mine shows three cases of gold of very fine character and great value. Altogether the value of this part of Placer's display is worth \$12,000, and it is one of the most attractive features of the entire mineral exhibit.

Placer county has its quartz as well as its drift and other mines. There is a fine collection from the Boulder mine, in the Opbir district, which shows also pieces of crystallized quartz of great beauty. The quartz specimens from the Boulder mine are typical of the mines of the county, which are of value and whose development has been considerable.

The Rocklin granite quarry has a display of its product, showing its character and suitability for building and ornamental purposes. From the Lincoln pottery of Gladding, McBean & Co. is a showing of its product, which includes sewer and chimney pipe, and all kinds of terra cotta goods, with fire brick and drain tiling.

The display that best illustrates the great variety of the mineral resources of Placer is the large exhibit of specimens, in three cases, of Alex. Keller, Auburn. They number about 500 specimens and are of great diversity and beauty.

Col. J. E. Doolittle shows a model of sluice box, grizzly and undercurrent used in hydraulic mining.

Several curiosities are shown, among them a granite mortar found 150 feet below the surface in a hydraulic mine at Dutch Flat. It was evidently ground out and used by a prehistoric people. A big striped boulder, with perfect stratifications, from the Red Point mine, attracts a great deal of attention.

The exhibit is in charge of Felix Chappellet Jr., who is courteous to visitors and well informed as to the resources of the county.

A summary of the exhibit is as follows:

Gold-bearing quartz and gravel from the Dore and Pioneer mines, the Osborn ledge and the New England mills; gold-bearing gravel from the White Quartz channel; pig iron from the Keller mine; gold-bearing cement from the Mayflower mine; gold-bearing gravel from the Hidden Treasure mine, and also from the Red Point, Mayflower and the Doolittle and Gould mines; gold-bearing quartz from the Drummond mine; nuggets from the Hidden Treasure, Morning Star, Power & Doolittle and Red Point mines; pottery from the works at Lincoln; granite from the Rocklin quarries; chrome iron from the New England mills; specimens of rim sand, petrified wood, striped boulder and an imitation gold brick representing the famous Harqua Hala bonanza (Arizona), weighing 5527.87 ounces and valued at \$96,237.27; Alexander Keller's collection, containing specimens of cabed rock, branded sandstone, brown jasper, volcanic marble, eupholite, airome, jasper rock, aloritic trachyte, cornelian agate, ring stone, serpentine porcelain, onyx, calcite, epidote on quartz, wall rock, mica, gold-bearing cement, quartz agate, pierolite and copper, manganese on quartz, magnetic iron, malachite, radiated calcite, fossil buckeye wood, andesite, ammonite, alphabetic porphyry, bent slate, glacial stones, baryte in wood fossil, carbonate of copper, gastoldite, blue quartz, red tourmaline, pottery clay, tremolite, banded slate, linerite, purple marble, rhodonite, wulgenite, fossil acorn, iron slag, pepperites, molybdenite, honey stone, iron sulphurets, mariposite, arsenical pyrites, tuzza, orthoclase, graphic granite, dogtooth spar, limonite, brocciated diabase and brown hematite.

Santa Clara.—The mineral exhibit of this county is wholly confined to a display from the famous New Almaden quicksilver mine. The exhibit is simple, but of value. It consists of a pyramid of cinnabar ore, from some of which the pure quicksilver can be obtained by hand, and of photographs of the various workings of these mines. The photographic display is, indeed, a very important and interesting feature. It shows not only the mines, including the surface and underground workings, but it presents a variety of views of the town, streets, houses and amusement places, showing finely the manner of daily life of the miners—their work and their play. One view, marked "An unusual occurrence," shows the town covered with snow—indeed, an unusual occurrence in low altitudes in this State. A large number of quicksilver flasks marked with the familiar "A" are shown. It is intended to place a quantity of quicksilver in a receptacle already prepared for the purpose and deposit cannon balls therein, giving a unique illustration of the high specific gravity of the quicksilver, for of course the balls will float.

AL. WEST, foreman of the Rosedale gravel mine, Tnolmme county, had one of his legs badly crushed just above the ankle, at about 4 o'clock on Thursday afternoon of last week. He and his partner were the only ones working in the mine at the time of the accident. Mr. West was in a squatting position and picking dirt from the top of a drift, when about two tons of material that became loosened fell, with the above result.

Slackens.

THREE mining claims in Humboldt district, A. T., have been sold for \$300,000 to St. Louis capitalists.

FROM West Kootenay, for 1893, there were shipped 246,869 ounces of silver and 2,072,370 pounds of lead.

AFTER a month's suspension for the placing of new boilers, the Virtue mine, in Baker county, has started up again.

A YOUNG man in one of the mining counties recently purchased quartz crystals from a swindler who called them diamonds.

THE *Record* says that Pioche, Nev., a town of over 1000 inhabitants, has no religious services of any kind, not even a Sunday school.

MR. TAYLOR D. MACLEON, the mining man, has gone to Arizona, where he has large interests. His address for several months will be at Yuma.

THE Omaha & Grant smelting pool has invited the Utah smelters to join the combination, and the miners of Utah are up in arms against the proposition.

J. L. DOWNING and R. L. Weaver, who left Cottage Grove, Lane county, Or., March 15th for the Bozeman mine are supposed to have perished in the mountains.

THE Homestake mine, in the Neal district, Eastern Oregon, has been sold to Denver capitalists interested in the Omaha & Grant Company. The consideration is \$60,000.

THE Nigger Ben mine, which has been "lost" for 30 years, its owner, a colored man, having been killed by Indians, has been rediscovered. It is in the Harqua Halas, in Arizona.

THE body of Henry Kreiner, a miner, well known in mining camps in southern California, was found on the Mojave desert. Kreiner had fallen from his wagon, and in the fall killed himself.

At a wedding in Camas Valley, Or., recently a duck was served whose craw was found to contain 25 cents worth of gold. The gravel bank frequented by the ducks will be prospected.

GOVANOS MCCONNELL has investigated the charges against Mine Inspector W. S. Haskins, in connection with the recent Bunker Hill and Sullivan accident, and declares them unfounded.

TAKING advantage of the low water in the Fraser and Thompson rivers in the bar below Government heads, British Columbia, a large number of Indians are said to be taking out \$6 a day each with rockers.

D. S. K. BUICK has sold the "Steam Beer" mine, near Leland, Josephine county, owned by J. C. Fullerton and John Rast, of Baker City. The purchaser is Elvin Nicodemus, of Chicago, and the consideration \$6000.

THE White Swan mine, Baker county, has been sold—consideration, \$125,000—and the purchasers are composed of a syndicate of Chicago capitalists, with headquarters at Baker City, and F. M. Johnson is the authorized agent.

W. H. CLARY of the Sheep Ranch mine warns prospectors to keep away from Calaveras county. The placers are worked out or all taken up, and it takes money to open up a prospect. He would do much better in the "pocket" counties of Tuolumne or Mariposa.

THE Boa Mining and Milling Company has been incorporated. Principal place of business, San Francisco. Capital stock, \$1,000,000, with R. H. Daly and T. M. Ferguson of San Francisco and I. L. Givens, H. T. Bradley and John T. Bradley of Oakland as directors.

DEEDS have been filed for record for the transfer of three mining claims in the Humboldt district, Ariz., the purchase price being \$300,000. The purchasers are St. Louis capitalists. Two or three other sales of gold properties have been consummated during the past week, the prices ranging from \$40,000 to \$250,000.

PLACER miners about Spokane will be interested in an effort being made to organize an association, somewhat on the plan of the Mining Exchange, for their especial benefit. It will have a double object: the dissemination of knowledge of modes of operating placers and their location in the northwest, and the advantageous sale and exchange of new discoveries.

LABOR COMMISSIONER MILLS' REPORT gives the following list of wages paid in Montana, the amount being per diem: Quartz miners, \$3.50; quartz-mill men, \$3.48; smelter men, \$2.88; coal miners, \$3.24; stationary engineers, \$3.78; stationary firemen, \$3.25; carpenters, millwrights, etc., \$4.18; bricklayers and stone masons, \$5.55; granite and stone cutters, \$4.92; painters and decorators, \$3.79; machinists, \$3.72; boilermakers, \$3.91; foundry employes, \$4.18.

THE Weber Mining and Milling Company, of Lakeview, Kootenai county, Idaho, has filed articles of incorporation. The object of the company is to construct and operate a quartz mill, reduction works and a power plant to operate the Weber group of mines in the Pend d'Oreille district. The capital stock is \$500,000, of which \$200,000 is subscribed. The incorporators are George A. Sheley, J. C. Dickinson of Detroit, F. A. Weber and S. P. Donnelly of Lakeview, and H. M. Casey of Hope.

THE Astronomical Society of the Pacific Coast held its annual meeting last week and elected the following officers for the ensuing year: W. W. Campbell, president; W. J. Hussey, first vice-president; William M. Pierson, second vice-president; John Dobbeier, third vice-president; C. D. Perrine, secretary at Mount Hamilton; F. R. Ziel, secretary and treasurer at San Francisco. The above officers and William Alford, E. S. Holden, E. J. Molera, J. M. Schaeberle and O. Von Geldern were chosen directors.

ASHLAND, Or., is preparing for a grand celebration in honor of mining developments. The programme includes a banquet to the miners at the Hotel Oregon and a free ball at the Opera House in the evening. The immediate cause of the celebration is the striking of a ledge by the Ashland Mining Company at its mine near town, which is taken as complete evidence of the permanency of the mining industry in that section. The company has been steadily at work since last fall boring a tunnel which has just completed tapping the ledge at a depth of 600

feet from the surface. The walls of the ledge are 30 feet apart, with an 8-foot body of quartz. The people have awaited with great interest the outcome of this work and Ashland is jubilant over the result. No other mine in Oregon has been prospected to an equal extent.

COL. C. C. THOMAS, the retiring superintendent of the Comstock Tunnel Company, was tendered a reception at Sontro on March 31st. A large delegation of the Colonel's friends was in attendance from Virginia, Dayton, Silver City, Empire and adjacent towns. During the evening Mr. H. V. Clinton, in a few well-chosen remarks, presented Colonel Thomas with an elegant watch chain and locket, the gift of the employees of the Comstock Tunnel Company, many of whom have been in the employ of Colonel Thomas continuously for over 14 years.

THE executive committee of the River Improvement Convention met at Sacramento and received the report of the delegation sent to Washington some months ago to work for an adequate appropriation for the improvement of the Sacramento, San Joaquin and Feather rivers. The members of the delegation gave personal recitals of their visit to the capital and of their exertions with members of Congress and the Government officials. The delegation secured a hearing before the House Committee on Rivers and Harbors, and had interviews with various members of the House.

JAMES F. WAANNEA, who has just come back from South Africa, has many interesting things to say of Californians now on the Rand. He says: "The California and Nevada men there—and there are hosts of them—are all doing well. John Hays Hammond heads the list. He is getting a salary of \$30,000 a year as consulting engineer for the Rhodes-Barnatto group. V. M. Clement, who was formerly at Grass Valley, is receiving \$1500 a month as superintendent of one of these mines. Captain Maine, formerly superintendent of the Treadwell mine in Alaska, is another Californian there who is doing well. Mr. Webber, who was prominently connected with different mines here, is now general manager of the celebrated Crown Wreath mine at Johannesburg. J. P. Connor is superintendent of the construction of machinery for the Rhodes-Barnatto mines. Perkins, who constructed the Tacoma smelter, is superintendent of the Guildenhans, or Golden Horse mine. Clanton is engineer of the City and Suburban mine."

Gaminetti as a Friend of Silver.

Representative Gaminetti of California has introduced in Congress a joint resolution authorizing the President to invite all of the nations of the Western hemisphere to a conference on the financial question. The preamble of the resolution recites the fact of the community of interests existing in the Western hemisphere, the continued depreciation of silver, the default by Guatemala, that Mexico and the Governments in Central and South America may take similar action, and asserts that the various interests of the United States are threatened with loss. Then follows the resolution. By it the President is requested to invite representatives of American republics to meet in Washington, whose object it shall be "to obtain relief from the conditions which have caused the demonetization of silver."

The second part is as follows: "The convention shall be for the purpose of drafting a treaty or treaties on the subject, to be thereafter submitted for verification to the several nations represented, calculated to secure to them such recognition of silver from the nations of the Eastern hemisphere and to provide regulations governing the production thereof and maintenance among themselves of such a standard as will restore permanent financial conditions and protect their common interests."

Reports received from various sources in Washington show that the depreciation in silver is being seriously considered in many quarters of the globe, and that the general discussion of proposed legislation in favor of the white metal is on the increase in several widely-scattered capitals.

The London Chamber of Commerce has submitted a memorial to the British Government praying for an international inquiry into the causes of the decline and fluctuation of the value of silver, and for relief from the embarrassment and losses suffered therefrom by British merchants doing business with the countries where silver is the common currency and standard of value.

Recently the Minister of Guatemala in London, under instructions from his Government, announced that the interest upon its bonded debt would have to be passed, on account of the low price of silver and the high rate of exchange. The Guatemala dollar, which had been worth from 75 to 79 cents, has dropped to 38 and 41 cents, and as the revenues of the republic are received in silver the interest on the bonds is practically doubled and the Government is made to pay 8 per cent interest instead of 4 per cent per annum. The bonds, which have been quoted from 55 to 60, dropped to 30 when the news was known.

Englishmen, who have an association of American bondholders in London, cabled their remonstrance to Guatemala and caused an investigation. They now claim that they have evidence to justify them in the opinion that the default of Guatemala is not due to any inability to meet her financial obligations, but is to punish England for her opposition to bimetalism and her responsibility for the decline in the value of silver by suspending silver coinage in India. The bondholders have asked the Government to intervene and enforce the payment of the interest when

due, and this is a question Lord Roseberry will have to meet.

Guatemala has entered no denial, nor is it thought that her Government desires to conceal the motive of her policy. Her justification will be that, by reason of the policy of Great Britain, the national currency of Guatemala is deprived of one-half its value and its obligations are thereby doubled. The subjects of the nation that is responsible for the situation must suffer. Great Britain may send down men-of-war to collect the interest on the debt for her bondholders, as they will doubtless request, but if she attempts force she will have to blockade every harbor south of the Gulf of Mexico and the Rio Grande, for the example of Guatemala is likely to be followed by most, if not all, of the Latin-American countries.

Similar action may be expected on the part of the Argentine Republic. Telegrams from Buenos Ayres contain unmistakable evidence that the action of Guatemala is approved.

Mr. Caminetti believes that by uniting all the American republics in one firm silver policy, great force can be exerted in favor of silver. It is thought the resolution will be adopted.

The Cœur d'Alene Snowslides.

The miners of the Cœur d'Alene region are suffering under an accumulation of misfortunes. The strike of two years ago and the recent enormous depression in lead and silver values had all but paralyzed the mining industry, but it had recently shown signs of reviving life and several of its important mines had resumed operations. Now another heavy misfortune is added to their already heavy burden. Tremendous snowslides have done much damage to property and caused loss of life and cessation of operations in several mines. The accident is so appalling and extraordinary that the circumstances will bear narration:

The snow had accumulated on the mountains at Canyon creek to a depth of fully 60 feet, and the late rains caused the huge mass to move at several places.

At an early hour March 29th a section of snow 300 feet in length, near the Black Bear mine, became detached and started down the steep mountain side. Before the inhabitants of the cabins in the path of the slide could flee the avalanche was upon them. Trees were torn up by the roots and boulders carried along by the mighty force; the whole shaking of the earth was as if an earthquake was in progress. Two families, together with their homes, were caught and carried along with the slide and buried out of sight at the bottom of the canyon. Others unaccounted for are also believed to have been killed.

Soon after the first slide took place another avalanche occurred farther up the canyon, near Burke. A family named Cbilson, consisting of father, mother and three children, heard the avalanche coming. Picking up the children, the frantic parents attempted to flee to a place of safety, but before they had gone 50 yards they were overtaken by the resistless mass of snow and crushed to death.

The snow is 40 feet deep and almost as solid as ice. The Gem, Frisco and Poorman mines turned out their whole force of miners to work for the recovery of the bodies.

Within a mile and a half above Gem are three other slides, one of them covering both railroads to a depth of considerable over 100 feet.

Some of the slides have been very destructive to flumes and railroad property, but the full damage will not be known before many days.

About 4 P. M., March 29th, a slide came down between Wallace and Gem, cutting off communication. Another one in Placer creek carried away a part of the electric light company's flume and light. Wallace is in darkness.

On March 30th the search party at the Black Bear snowslide worked all day without result, but just at dusk discovered the body of Martino Michele, an Italian miner who was stopping with the Deiro family. The bodies thus far found are: Mrs. Deiro, aged 25; Victoria Deiro, her daughter, aged 5; Mrs. Nellie Rowe, aged about 35; Martino Michele, aged 24. Other bodies have since been found. The total loss of life was about twelve.

All the buildings and furniture were literally smashed to atoms and were carried forward 20 to 40 feet in the direction of the slide.

The damage to business is serious. The railroads cannot be operated until the obstructions are removed, and some of the mines must shut down in consequence. The Standard has already done so. The Frisco flume has been carried away in four places, aggregating 1300 feet. This closes down that mine until the repairs can be made. The Union Pacific suffers much more than the Northern Pacific, as all the slides are on their side of the canyon. Burke depends mainly on the railroads for its wood supply. The Northern Pacific has brought over a snow plow and

commenced to remove the slides. The roads will surely be blocked for a week, and possibly much longer. The Poorman mine was to have started up April 1st. This will doubtless delay work there, and may close down the Tiger mine, as they have no room for storage of concentrates.

A New Chlorination Process.

A description of a new process of chlorination, invented by Mr. J. W. Sutton, of Brisbane, Australia, is thus given by *Industries and Iron*:

"The chlorination used in these trials consisted of a wrought-iron barrel lined with lead, through which passed axially a perforated tube lined with asbestos. Attached to this barrel was placed a smaller one, also lined with lead, and fitted with a steam jacket in such a manner that both barrels could be rotated by the same gearing at the rate of about five revolutions per minute. The damp ore is placed in the large barrel, and a charge of manganese dioxide, salt and sulphuric acid in the smaller one before commencing operations. In this way the ore as it is rotated in the larger barrel is saturated with chlorine as it issues from the central tube, and when the evolution of gas becomes slow the steam is turned on to the jacket, and thus ensures the complete decomposition of the salt. Valves in the barrels are opened at starting, so as to allow of the exit of the enclosed air, and guarantee a strong chlorine gas acting on the ore. Three hours' treatment has been found sufficient for the dissolution of the gold in the Mount Morgan ores, and at the end of this time the contents of the barrel are run into a leaching machine, which is a centrifugal similar to that used for drying sugar. This method of leaching is found to be most economical of water, and seven minutes only are required for leaching a charge of 10 to 20 cwt. of ore. At the end of the leaching operation a small mechanical plow removes the spent ore from the centrifugal into trucks or into shoots leading to the waste tailing heap. The gold is recovered from the solution in a precipitating tank of rectangular shape, through which a spindle is driven from corner to corner. Kerosene oil and sulphate of iron are added to the leachings in this tank, and the precipitation of the gold is completed in ten minutes. A tap in the precipitator is then opened, when the water and base metals run through a sand filter and the oil containing the gold in suspension passes into another small centrifugal, where the oil is immediately separated and ready for use over again, while the gold remains in the basket, from which it is scooped out and melted. Those of our readers acquainted with the Hall and Richards process, which hitherto has been in use at Mount Morgan, will see that the new process has many points of dissimilarity to it, and saves not only the bother attending the burning of the charcoal filters, but also marks a great improvement in the methods of leaching adopted in older processes. In addition, no amalgamation is necessary, as the gold separated from the oil is ready at once for the melting crucible, and the ore, unless it contains a large quantity of mundic, can be treated without any previous roasting, since the chlorine is delivered to the ore in an undiluted condition. The cost is stated to work out at 6s. per ton."

SENATOR WOLCOTT has introduced the following resolution in Congress: "That the President of the United States be requested to enter into negotiations with the Republic of Mexico, with a view to encourage and extend our commercial relations with China and other Asiatic countries, looking to the coinage at our mints of standard Mexican dollars, under proper agreement with Mexico as to the seigniorage, method and amount of coinage, and to report the result of his negotiations to the Senate." This resolution was agreed upon at a recent conference held at Senator Wolcott's house, in which Senators Dubois, Shoup, Teller and other Senators from the silver States participated, and it was then agreed that a resolution to this effect should be drafted and the issue raised as to whether the President and Congress would consent to enter into negotiations with Mexico looking to the coinage of Mexican silver dollars by our mints at San Francisco and Carson, and thus afford a market for the American silver product.

Foundry Notes.

THE Spring Valley Water Works will build a reservoir on top of Clarendon Heights, south of Golden Gate park, and on Saturday gave the contract for erecting the reservoir to the Union Iron Works. It was proposed to give this reservoir a capacity of from 350,000 to 500,000 gallons. The contract calls for a steel reservoir of the capacity of 500,000 gallons, and it will be placed at an elevation of 600 feet above. The site is a little less than two acres in extent, and this elevation insures water facilities for a large area of country at present unavailable for residences purposes. This plans for a pumping station are being prepared.

BAKER CITY is considering a proposition from an Eastern syndicate for this section of a smelter.

The Coxe Movement.

The Coxe movement is developing unexpected vitality. The original division, with Coxe and Carl Browne in command, has more than doubled its numbers in a week's march, and is now at Pittsburg. The other division, which left Los Angeles three weeks ago, and which, at the time of last week's report, was stranded in a Texan desert, has gotten as far as Arkansas and is gaining accessions to its ranks. Encouraged by this success, new companies are springing up all over the country. A second division, of 125 men, left Los Angeles on Monday, and a division 600 strong left San Francisco on Tuesday of this week. These several divisions expect to meet at Washington about May 1st, and it really looks as if they would make a crowd formidable in its numbers. Coxe declares that the army will camp before Washington 250,000 strong, while dispassionate judges admit that perhaps one-fourth of that number may get there.

As this curious army increases in numbers it improves in quality. The pioneers in the movement, both in California and Ohio, were mere tramps, but the recruits are of better character. A good number of respectable farm laborers and mechanics have joined Coxe; and of the company which left Los Angeles on Monday about twenty per cent were heads of families, and nearly all were of a respectable sort. The accessions to the first California detachment since it reached Texas are said to be superior to the original rank and file. At various points in the East, unemployed and striking mechanics are forming into companies and will join the forward march when the column reaches them. A very notable fact in connection with this strange movement is the reception accorded the "Commonwealers" by the public. In many places they are entertained as public guests, and everywhere they are liberally provided for. The novelty of the thing must largely account for this, but when reduced to the last analysis, there appears an element of sympathy for the movement in spite of its absurdity.

In a statement put forth by "General" Coxe we have a full explanation of the purposes of the "army." Coxe, it appears, is a man of some property, who believes that the prevailing hard times are due to contraction of the currency; and who further believes that no possible harm can come of an indefinite inflation of the currency. He wants a law authorizing every municipal corporation in the country to issue or receive paper money up to one-half of the value of the taxable property it contains. This money he proposes that the municipal authorities shall spend in the employment of labor upon public works. As only Congress can enact the laws necessary to carry out this scheme, he proposes that the unemployed shall march to Washington and demand relief. "A quarter of a million men clamoring for work," he says, "is a petition that cannot be thrown into the waste-basket."

Of course, the folly of all this is beyond words. The march to Washington is a crazy movement in support of a crazy scheme; and yet as we see in the incidents of the movement above outlined, it has a definite and increasing strength and commands a species of sympathy from the public. It is easy to denounce and to rail and to threaten, but it is better worth while to inquire into the sources of this strength and sympathy, and it appears not unlikely that they will be found to lie in the hardship and injustice of a financial system against which the Commonwealers are in an instinctive though grotesque revolt.

Fish Display at the Fair.

The next feature of the competitive-exhibit order at the Fair will be a display of the fish industry, from April 5th to 12th. Space has been provided for this exhibit in the arcade in front of the Agriculture and Horticulture Building. A number of tables will be placed there for the purpose, and the fish will be taken directly to the Exposition grounds and placed on ice on these tables.

It is proposed to make it one of the prominent features of the Fair, and the fish of all countries, as well as of the Pacific coast in general, will be shown. There will be fresh, smoked and salt fish. Few people realize the amount of capital involved in this industry on the Pacific coast. As is probably well known, salmon constitutes the chief branch of it, and last year over \$5,000,000 was expended in catching, packing and shipping this one variety. The total value of fish passing through San Francisco amounts to over \$6,000,000 annually. The codfish exhibit will not play a prominent part in the proposed competitive display, but will have special arrangements made for it later in the season, or at such a time when the condition of the fish will permit.

The Irrigation Movement.

Active preparations are now being made for the next National Irrigation Congress to be held about September 15th, at some point in the West not yet determined on. The last Congress, which was in session about a week in Los Angeles, October, 1893, appointed commissioners in every Western State and Territory, whose duty it is to prepare a report to be submitted to the coming Congress covering all the features of special interest in each State and Territory of the arid West. These reports will show the amount of arid and semi-arid land; the amount of land now irrigated, and the acreage believed to be irrigable; the sources of water supply, developed and possible of development; the cost of procuring, storing, and delivering water on lands; State legislation, in force and needed; national legislation as to the disposition of arid lands and Government control of water sources; and such other points as may suggest themselves to each commission as being pertinent to their own State.

Apex and Side Lines.*

The Supreme Court of the United States has lately decided a case of unusual importance to prospectors and mine owners. It is popularly known as the Amy-Silversmith case and involves the right of the owners of veins or lodes in such part of them as may extend, in their course downward, beyond the side lines of claims.

There has been no dispute as to the right of the owner of a claim to follow his vein into the earth as far as it extends beyond the side lines of the claim where the apex of the vein crosses both of the end lines. The following diagram illustrates such a case:

But there has always been a controversy as to what are termed the extra-lateral rights of a lode owner, where the apex of his vein does not cross the end lines, as in the following case:

In the above diagram it will be observed the vein crosses what are called the side lines of the claim instead of the end lines. In such a case, has the owner of the claim any extra-lateral rights in his vein? That is, can he follow and appropriate his vein in its downward course beyond the side lines of his claim and, if he can, to what extent?

Heretofore the State courts, as well as the courts of the United States, except the Supreme Court, have held that the vein in such a case can be followed. The only dispute has been how and to what extent?

Most of the courts, including the United States Court in Denver, have ruled that in a case such as the last diagram gives, the claim owner may draw in the end lines of his claim to the two points where the apex crosses the side lines, and that he may follow the vein indefinitely into the earth within planes formed by the new end lines extended downward and indefinitely in their own direction. Thus, using the last preceding diagram and drawing in its end lines as suggested, the following would appear:

Under the rule referred to, the claim owner in the case of the above diagram could follow his vein outside of his side lines with the vertical planes as indicated by the new end lines and the dotted lines extended from them.

A few courts had adopted a different rule, to the effect that the true strike of the vein should be ascertained and the vein could be followed beyond the side lines between vertical planes projected at right angles to the strike at the points where the vein on its true strike crossed the side lines. But the former rule was most generally accepted and seemed to strike both bench and bar as more nearly comporting with the intent of the mining statutes.

But now comes the United States Supreme Court in the Amy-Silversmith case and effectually annihilates both rules. It holds in plain and unmistakable terms that the owner of a mining claim where the apex of his vein crosses the side lines of the claim and not its end lines, has no extra-lateral rights whatever in his lode. That is, he is confined to that part of his vein which is within his claim, and he cannot follow it outside of the lines of his claim at all.

The Amy claim was a parallelogram, 1470 feet long and 491 feet wide. The side lines and the end lines were parallel. The vein ran at an angle through the claim, crossing both side lines. The Non-consolidated claim joined the Amy. It was triangular in shape.

The owner of the Amy claim followed his vein beyond the Amy side lines into the Non-consolidated claim and extracted and sold a large quantity of ore therefrom. The question was as to the ownership of the ore and that part of the Amy vein within the Non-consolidated claim. The court held that the Amy owner had no right whatever to

them and that they were the property of the Non-consolidated owner. This is its language:

The difficulty in the present case arises from the course of the vein or lode upon which the Amy location was made. It is evident that what are called side lines of the location, as shown in the diagram, are not such in fact, but are end lines. Side lines, properly drawn, would run on each side of the course of the vein or lode, distant not more than 300 feet from the middle of such vein. In the Amy claim the lines marked as side lines cross the course of the strike of the vein and do not run parallel with it; they therefore constitute end lines. It is true the lines are not drawn with the strict care and accuracy contemplated by the statute, and which could only have been done with more perfect knowledge of the true course or strike of the vein from further developments. But, as was said by this court in *Iron Silver Mining Co. vs. Elgin Mining Co.* (118 U. S. 196, 207): "If the first locator will not or cannot make the explorations necessary to ascertain the true course of the vein and draws his end lines ignorantly, he must bear the consequences." The court cannot become a locator for the mining claimant and do for him what he alone should do for himself. The most the court can do, where the lines are drawn inaccurately and irregularly, is to give the miner such rights as his imperfect location warrants, under the statute. It cannot relocate his claim and make new side lines of end lines. Where it finds, as in this case, that what are called side lines are, in fact, end lines, the court, in determining his lateral rights, will treat such side lines as end lines and such end lines as side lines; but the court cannot make a new location for him, and thereby enlarge his rights. He must stand upon his own location, and can take only what it will give him under the law.

Acting upon this principle, there is no lateral right in the holder of the Amy claim by which he can follow its vein into the Non-consolidated claim. Mistakes in drawing the lines of a location can only be avoided, as said in the case cited, by postponing the marking of the boundaries until sufficient explorations are made to ascertain, as near as possible, the course and direction of the vein. "Even then," the court added, "with all the care possible, the end lines marked on the surface will often vary greatly from a right angle to the true course of the vein; but, whatever inconvenience or hardship may thus happen, it is better that the boundary places should be definitely determined by the lines of the surface location than that they should be subjected to perpetual readjustment according to subterranean developments subsequently made by mine workers. Such readjustments at every discovery of a change of the course of the vein would create great uncertainty in titles to mining claims."

Applying this doctrine to the case before us, it follows that the vein in controversy, the apex of which was within the surface lines of the Amy claim, did not carry the owner's right beyond the vertical plane drawn down through the north side line of that claim. The Amy claim had no lateral right by virtue of the extension of the vein through what was called the north side of the claim, and that side line so called was, in fact, one of its end lines.

The Amy decision settles the question that has been in dispute so clearly that there will be no room for controversy over it hereafter. In doing this it reverses the rules adopted in similar cases by all judges in the mining States and Territories, and for that reason the decision is of vital moment to the mining interests.

But there is another class of mining locations which it seems must be seriously affected by the decision also. It is where the apex of the vein crosses one side line and one end line. The following diagram presents the case:

The courts have heretofore held that in such a case the owner of the vein might follow it beyond his side lines, and that to determine what extent of it he might thus follow the end line which the vein did not cross should be moved up to the side line, and so much of the vein as was within the claim might be followed within the vertical planes formed by the stationary end line and the one moved up.

But the doctrine of the Amy-Silversmith case followed to its logical conclusion must reverse this rule also. To sustain the rule the court must "become a locator"—a thing which the Supreme Court says it cannot do. Says the court: "The court cannot become a locator for the mining claimant and do for him what he alone should do for himself." If the court cannot move up two end lines where the vein crosses both side lines, how can it move up one to meet the point where it crosses one of the side lines? In the case of a vein crossing one side line it is as much the

location of a claim by the court to move up an end line as where it crosses both. The *News* believes that whenever the Supreme Court of the United States has before it the case of a vein crossing one side line and one end line it will hold precisely as it did in the Amy case: That the owner cannot follow the vein outside of his vein wholly within the limits of his claim. In other words, to entitle the claim owner to follow his vein outside of his claim the apex of the vein must cross both the end lines of his claim.

This rule will impose some hardships and greater care upon the locator, and it is well for him to understand precisely what the highest court of the land requires and what it is likely to require at his hands in the location of claims.

Silver-Lead Smelting Practice.

In Two Parts—Part II.

Walter Renton Ingalls in *Engineering Magazine*.

Of course the ideas of metallurgists as to the best slags and other details vary, though within narrow limits. A very general type of slag in the Rocky mountains is a silicate, so-called, with 30 per cent silica, 40 per cent ferrous oxide, and 20 per cent lime. The specific gravity of the lime should not exceed 3.6, in order to have a good separation from the matte; so, although the fluidity of the slag increases with the percentage of iron, the latter cannot exceed a certain limit without danger of loss of silver and lead through its higher specific gravity. The lead in the charge should amount to 12 per cent, although within the past two or three years smelters who used to think they should have 15 per cent have been obliged to run as low as 8½ per cent, owing to the scarcity and increased cost of lead ore. The tenor of the charge in precious metals should be such as to make bullion with about 300 ounces of silver and one ounce of gold per ton. A good slag should not, then, carry more than 8-10 ounce silver per ton, and ¾ per cent lead.

The losses in silver-lead smelting occur in various ways, the most important being in the slag, which, however poor, carries away a large amount of the valuable metals, owing to its great volume. The loss in slag is increased in smelting charges high in zinc or low in lead, and of course also by irregularities in the running of the furnace. A certain amount of lead and silver is lost, moreover, by volatilization in the form of dust, especially with zincy ores, although a part of this is condensed and collected as fume and dust in a long series of flues or chambers and subsequently re-smelted.

The losses in smelting are taken into consideration, as a matter of course, in buying the ores. Thus only 95 per cent of the silver is paid for, while the gold brings \$19 or even \$20 per ounce. The lead is bought on fire assay, which is smelting in miniature and gives results analogous to those of the blast-furnace, but a sufficient discount is made in the rate of payment, based on the New York quotations for refined lead, to give the smelters a safe margin for refining and freight to the seaboard. The smelter looks for his profit in the charge for smelting, which varies according to the character of the ore.

The furnaces universally used in the Rocky mountains for lead smelting are rectangular shafts of fire-brick supported on iron columns which rest on a solid foundation, with a tapering bosh of hollow iron castings (water jackets) standing on a hearth of refractory material. Inside the hearth there is a crucible, forming the bottom of the furnace, connected by a siphon-tap with an external lead-well, into which the molten bullion drains and from which it is cast into bars. The slag and matte are drawn off from the front of the furnace, through a tap-hole, into large pots, where the matte settles while the slag overflows into smaller pots on wheels, in which it is carried to the waste-dump. A series of tuyeres enter the furnace at ends and sides, passing through the water jackets and protruding slightly into the bosh. The blast for smelting is thus distributed from a large pipe surrounding the furnace, which is connected with the main pipe from the blowing engines. From the top of the furnace above the charging door, the fumes are carried through a large pipe called the "down-comer" or "down-take" to the flue-dust chambers; or the furnace may be quite open at the top, level with the charging floor, in which case the fumes go off through a down-take immediately under the feed floor. The latter style of furnace is the more modern and generally approved.

The modern American lead furnace is from 30 to 42 inches wide, and 86 to 120 inches long at the tuyeres. The distance from the bottom of the crucible to the tuyeres is 30 inches, and from the tuyeres to the charging floor it is 12 to 18 feet, the height depending upon the strength of the blast. As to the latter some metallurgists advocate a blast ¾ to 1 inch pressure of mercury, and others 2 to 2½ inches.

The history of argentiferous lead-smelting in the United

* The Rocky Mountain *News* contains the above in relation to the decision of the Amy-Silversmith case. It was written by a leading Colorado lawyer and is worthy of confidence.

States since its inception at Argenta and Eureka has been a record of steady improvement, until at the present time the art has been brought to a higher degree of perfection than exists elsewhere in the world. The first furnaces built, either of the Pilz (round) or Raschette (rectangular) type, were of very faulty construction, and were capable of only a brief campaign, partly on account of errors in their design and partly owing to the fact that good fire-brick was unobtainable. Charcoal, of inferior quality, was the only kind of fuel used. There were few skilled metallurgists, and even their knowledge of scientific furnace-work was vague, smelting being carried on principally by rule-of-thumb methods. Under these conditions it is not surprising that the cost of smelting and losses in slag were high. In Eureka, in the early days, it cost \$20 to reduce a ton of ore, and losses of 40 per cent of the lead and 30 per cent of the silver are reported.

The first great improvement in the art was the introduction of the siphon-tap by Albert Arents, which revolutionized the methods of discharging products from the furnaces. This was followed in 1876 by the investigations of Anton Eilers, now at the head of one of the largest smelting companies in the United States, on the subject of lead-slugs, which was continued by Hahn, Iles and other metallurgists. Smelters then began to calculate their charges with something like accuracy, and the furnace-running was vastly improved. About the same time came the general introduction of water-jackets, which had been invented some years previously, replacing fire-brick at the smelting zone of the furnace and increasing its life. The construction, size and form of the furnace had also been improved in other respects during this time, so that the length of campaign was extended and the cost of smelting was reduced. These improvements had all been made before smelting assumed important proportions at Leadville, Colorado, but the work at that place, notwithstanding the easily reduced lead carbonate ore which its mines were then producing, was very far below the present standard. The cost of smelting in 1880 at Leadville averaged \$15.25 per ton, and treatment charges on ore \$22 per ton. The average grade of the ore smelted was 69.5 ounces per ton silver and 22½ per cent lead, about 96 per cent of the former and 88 per cent of the latter being saved.

Since the rise of the valley smelters, developments in the lead-smelting industry have been rapid and important. The concentration of works into a few large plants and the handling of larger quantities of ore in each have reduced general expenses; labor-saving devices have been introduced for handling ore, slag, matte and bullion; furnace-work has been brought to a higher degree of perfection than exists in Germany, where many of our best metallurgists were trained; and the furnaces themselves have been improved vastly in construction and size. Where furnaces 24 inches square at the tuyeres, smelting eight or nine tons of ore per 24 hours, were used in Eureka 20 years ago, we now have furnaces 120 inches long and 42 inches wide, smelting 80 tons. Instead of losses of 40 per cent in lead and 30 per cent in silver, as much as 94 per cent of the lead is recovered, and it is bad work indeed if 95 per cent of the silver is not saved—and this with charges running only 9 or 10 per cent in lead against 40 to 48 per cent in Eureka. Instead of a cost of \$20 per ton for smelting, we have an average in Denver of only \$4.50 per ton, for a neutral ore (not including roasting, which costs less than \$2 per ton).

The old type of round furnaces, still used almost entirely in Germany, has nearly disappeared in the United States, having been replaced by the modern rectangular furnace, itself the successor of the Raschette. This change has come about because the smelting capacity of a furnace is limited by the distance between the tuyeres, which it is agreed should not exceed 42 inches, wherefore a rectangular furnace can be built, obviously, with greater capacity than a round furnace.

Important changes have occurred in the past five years in the character of ores treated. The easily smelted carbonate ores of Leadville have been gradually exhausted, and smelters are now obliged to look for their lead in the sulphide of ores of Bingham and the Cœur d'Alene, which require, more or less, a preliminary roasting. The quantity of iron sulphid ores and concentrates in the market also has increased, and this class of ore is bought freely by the smelters, with whom it replaces a certain amount of oxide of iron flux, which has to be brought chiefly from Leadville, on unprofitable terms. Now all the large smelting works are equipped with roasting furnaces, where formerly they had none, and mechanical furnaces, like the O'Hara and Pearce, are being introduced in place of the old form of reverberatory furnaces; sulphide ores are now the common, and oxide ores the rare, class of material which come to market.

At the present time we cannot see great improvements that can be made in our practice of lead smelting. The general arrangement of the works is good, and the me-

chanical devices for handling products seem to be complete. The construction of the furnaces does not seem likely to undergo radical changes unless it is possible, as Professor H. O. Hoffman suggests, to substitute some suitable refractory material, such as coke-brick, for the water-jackets, which abstract a good deal of heat. The present state of furnace metallurgy, also, leaves little to be looked for in these days when fierce competition has forced every man to do his best. Still it can never be said that perfection has been reached, and the future may bring new and important developments, but it may be confidently asserted that the changes in the next ten years will not be so revolutionary as in the last.

American Improvements and Inventions.

Discussion by Prof. H. O. Hoffman, Boston, of a Paper Read by James Douglas, New York, before the American Engineering Congress.

In his review, Mr. Douglas has necessarily compressed a very large subject into very small compass. I should like to add a few supplementary remarks on the treatment of argentiferous lead ores.

First as to sampling. This has been brought to great perfection within the past seven or eight years, by reason of the fact that a few large smelters, centrally located for ores, fuels and fluxes, have replaced many of the smaller ones which formerly existed. In the latter, hand-sampling with the ordinary implements or with improved ones, like the Brunton sampling shovel, was sufficient; but in the large works a more rapid and less expensive method became necessary, and machine sampling was introduced. This consisted at first in separating continuously a small part of a running stream of ore; afterward it was found better to take the whole width of the stream at short intervals of time. Of the machines for doing this, the three representative ones are those of Brunton, Bridgman and Constant, all excellent. To prepare the sample for the laboratory, we have the sample grinders of the coffee-mill type, as made by our leading firms, and the quartering apparatus (laboratory samplers) of Bridgman and others.

Coming to the calcination of ores, special attention must be called to the improved construction of the furnaces and to the making-up of the charges. In the stationary hearth-furnace, besides increasing its inside width to 16 feet, the roasting-hearth has been separated from the fusing-hearth by a vertical flue, and the area of the vertical section of the latter has been made smaller. The products of combustion passing from the fireplace over the small fusing-hearth rise in the flue and then suddenly expand, filling the entire width of the roasting-hearth. Thus it has been made possible to keep a high heat in the fusing-hearth and a low heat in the roasting-hearth, and to let the latter discharge into the former. With mechanical rables the roasted ore is collected in a hopper, which is emptied at intervals into the slagging-hearth. In the making-up of roasting charges, new problems had to be solved. In foreign works the ores to be slag-roasted are galena concentrates rich in lead, while the sulphide ores which our Western smelters have to treat are usually mixtures, low in lead, of pyrite, blende, galena, etc., and gangue. To slag these requires a high temperature, which is liable to cause loss of lead and silver by volatilization; and, as an entirely satisfactory method of condensing the fumes from a slagging furnace has not yet been devised, the only way of reducing the loss seems to be not to slag charges containing over ten per cent of lead and 100 ounces of silver to the ton—some metallurgists say even less.

In the shaft-furnace, the form and the material used are much alike at all works. While 42 by 120 inches is now a common size, some smelters think 33 by 100 inches the most favorable for doing clean and cheap work. Formerly the standard distance between the tuyeres was 36 inches. The natural tendency to increase the capacity of the furnace prompted its extension to as much as 60 inches, water-cooled tuyere nozzles being allowed to protrude through the water-jackets, so as to make the actual distance 48 inches. The pressure from the strong blast necessary to penetrate a charge of such thickness made the heat in the furnace creep up, with the result of excessive loss in metal. This caused a reaction, and the distance was reduced in some instances to 30 inches; at present it varies from 33 to 42 inches. Some furnacemen think 120 inches too long for a furnace, and do not like to exceed 100 inches.

In the management of a furnace, beside the making of a correct slag, its separation from the matte, especially with zincy ores, and the collection of flue-dust, have given much trouble, and are still doing so to some extent. Mr. Douglas praises the Mathewson tapping-jacket as promoting a good separation, but omits to mention that of Mr. E. F. Eurich, which resembles it very much. Dr. Iles accomplishes the work in an entirely different way. He collects the liquid matte and slag from six blast furnaces (42 by 120 inches) in a reverberatory furnace heated by a separate

fireplace. Matte and slag are not only well separated, but their further handling is greatly cheapened. It would seem as if, with a smaller number of furnaces and a continuous flow, a Herreshoff or Orford well, or, if necessary, a combination of the two, would give a satisfactory separation. For the collecting of fumes, the simple and effective manner of cooling the walls of dust-fines and dust-chambers in use at the Grant and Omaha Works, Denver, Colo., should not be overlooked. I refer to the use of hollow bricks, through which air circulates. It is a simple and excellent way of surmounting one of the principal difficulties in condensing flue-dust, namely, the cooling of the gases; the other—the retarding of the current—has been happily dealt with by Freudenberg. In the management of the furnace, special stress must be laid on the fact that the making-up of the charge is now almost wholly governed by chemical principles, instead of mere experiment as in former years. For this introduction of a scientific instead of an empirical method, the American lead smelter can take much credit to himself.

The improvements made in the desilverization by the refiner are in no degree inferior to those made by the smelter, and have been along the same line. The distribution of precious metal in the base bullion has been carefully studied, and methods of sampling have been devised which are accurate and quick. Here, also, in some instances, machine work has replaced hand work. In the general arrangement of plant, the apparatus and its management are so planned that the base bullion, when charged into the softening furnace at the top of the works, is not handled again until it is ready to be loaded at the lower end, as refined lead, into the cars. The bars are moulded, not by ladling, but by some one of the several simple mechanical devices for that purpose. The capacity of the desilverizing kettle, by which that of the remaining apparatus is regulated, has been increased from the original 12½ tons to 30, and in a few instances to 45 and 50 tons. The kettle is discharged by that simple and beautiful invention, the Steitz syphon. The manner of working is being continually simplified. To-day, base bullion, running 300 ounces silver and gold to the ton, is desilverized by two sinkings, if no separate gold crust is to be made; otherwise by three. The liquation of the crusts has also been greatly improved; and retorting, although invented by Parkes many years ago, only became the established method of work after it had been perfected here by Balbach. In cupelling, the principle of the English furnace has been adhered to; but the form, size, filling and manner of support of the test, the apparatus for blowing, the mode of working, etc., all have been so changed and improved as to make an entirely new furnace, suited to the daily increasing demands made upon the refiner. In the record of improvements the working up of by-products must not be forgotten. This is now done as fast as they are made, thus leaving only a comparatively small amount of metal circulating in the works.

All the splendid achievements of American lead-smelting and refining have been made within the past 30 years; and, without disparagement of the labors of any others who have contributed to this result, I think we may well recall the names of O. H. Hahn and A. Eilers among smelters and E. F. Eurich and the late A. Steltz among refiners as pioneers of improvement—all of them members of the Institute.

Gold Mining in the Colony of Victoria.

The following note on the Bendigo gold field, Victoria, is compiled from a report of E. J. Dunn, F. G. S., to the Secretary for Mines, Melbourne. The city of Bendigo, around which gold workings extend for several miles in all directions, is about 100 miles northwest from Melbourne. Its longitude is 144° 16' 39" east, and latitude 36° 45' 10" south.

In the valleys the operation of extracting the gold from the alluvial deposits reaches a depth of from 10 to more than 100 feet; in the flats and gullies these deposits are only shallow.

Two large boards of alluvial gold which are scattered through the shallow gravels of the gullies and creeks around Bendigo were, in Mr. Dunn's opinion, gathered from the surrounding rocks by denuding agencies.

The gold obtained by mining in the gold field is found chiefly in the lower slurian strata, which extend over an area of 435 square miles. Of this area the Bendigo gold field occupies an area of about 140 square miles, the length being 20 and the width 7 miles. The strata are much contorted and corrugated, forming no less than eleven anticlines in a width of 10,000 to 11,000 feet, the center one being called the New Chum. These axial lines run pretty uniformly through the gold field for a distance of seven or eight miles. Mining is carried on very systematically and to a very great depth. The Lazarus Company, on the New Chum line of reefs, have sunk a shaft to a depth of

2209 feet below the pit bank. From this shaft, crosscuts or tunnels have been driven across the measures at right angles to the axial lines. Twenty-five crosscuts have thus been driven at this mine at different depths—the first one being at 199 feet 7 inches, the lowest at 2209 feet. In this shaft, gold reefs, quartz or spurs have been found and mined more or less all the way down.

At the North Johnson's mine, a shaft has been put down to a depth of 1642 feet 6 inches; from this shaft crosscuts or tunnels are driven across the measures at right angles to the anticlinal lloes, at different depths, by which the quartz reefs and spurs are intersected and mined. In addition to these there are numerous other shafts.

Each of the axial lines referred to contains several reefs, lying one below the other. The most peculiar feature about the quartz veins of the district is the occurrence of the so-called saddle reefs. These are bodies of quartz of lenticular form that are bent over the axial lines, both anticlinal and synclinal, but only to a moderate extent are they found along the synclinals. The saddle reefs are of great size in places, of remarkable persistence in length, and are also notable for recurring in depth one below the other.

Although mining operations have been carried on in this gold field somewhat extensively during the past 40 years, the extent of ground so far mined is insignificant compared to that which remains to be developed.

Auriferous Beaches of New South Wales.

The Evans river, known locally as the Little river, rises in the parish of Riley, county Richmond, New South Wales, half a mile to the south of the township of Woodburn, New South Wales, and flows to the east into the Pacific ocean. For many years gold has been won in patches along the coast from Port Macquarie to the Queensland border; and deposits have been described by the late C. S. Wilkinson in various reports. At Ballina the occurrence is of special interest, as the precious metal has been derived from the denudation of a sheet of basalt, which has been proved by bulk crushings to be auriferous. A description of the formations, made by George A. Stonler, geological surveyor, for the government, will be of much interest to the beach miners of this coast.

On the northern bank of the Evans river there is a wide, somewhat fan-shaped flat, which extends to the Richmond river, and is formed partly of fresh-water alluvium (the rich agricultural soil of the district) and partly covered by blown sand. To the southwest of the Evans river there is an extensive development of the sandstone and shale of the Clarence coal measures, which, with a boss of felsite, form a large headland at the mouth of the river, with the bold outcrop characteristics of the sandstones of the measures. Coming south the rock is lost under a coverlog of blown sand, which occupies, at a distance of three miles from the river, a fairly large area, and is arranged in lines of dunes, which attain, in one instance, a height of 130 feet and are sufficiently continuous to be termed a range, while others are in the form of ridges and eminences separated by swampy flats. They are of somewhat rounded outline, and are mostly covered with heath, which binds the surface of what would otherwise be shifting sands. These æolian deposits occupy an area somewhat lozenge-shaped and measuring about three miles in the greatest width, and having a length of seven miles as far as examined; they are bounded on the west by sandstones, etc., of the coal measures, and at Bullock creek, above the center of the area, there is a small outlier of slate of lower carboniferous (?) age.

Gold has been obtained from three distinct deposits, which are giving employment at the present time to about 50 miners.

(1) Present sea beach. After each tide a certain quantity of black sand containing fine gold and platinum is found to have been thrown in streaks upon the beach, but as the amount of the deposit depends upon the favorable conditions of wind, tide and weather, it is only at intervals that the sand is worth working. The uncertainty of the waves bringing up a fresh and workable quantity of sand for a considerable period of time makes the occupation of a comber precarious; and as there is no great labor entailed, the beach can be kept fairly combed by the settlers in the immediate neighborhood. The beach is narrow and inclined, and is often quite covered by the surf.

(2) An auriferous deposit of black sand has been worked in patches for a length of about two miles. A fairly large amount of gold has been won—it is said that one small property yielded 1000 ounces of gold—and although there are two or three claims with a couple of months' work in sight, the bulk of gold in the deposit has been extracted. The stripping consists of a loose sand, varying in thickness from three to sixteen feet. I had no opportunity of measuring the thickness of black sand, as none of the claims were in full work.

(3) Some six months ago Messrs. Nobbs and McGeary were prospecting a quarter of a mile inland from the coast, and discovered a deposit of auriferous black sand, which is about six feet above ordinary high-water mark, and has probably been formed in the same way as the two deposits already referred to. The "terrace" has been traced for some four miles in length, and though doubtless continuous at one time, it has been denuded, and now occurs in outlying patches, of different lengths and with a maximum width of 100 feet, which are covered by drift sand varying from a few feet to 25 feet in thickness. The black sand measures from one to five feet in thickness, and has a decided dip seaward; it is thickest in the center, and thins off at both sides. In color it varies from whitish gray to black, according to the amount of iron present, and it consists chiefly of minute grains of quartz and a little topaz, fine specks and pellets of ilmenite (titanic iron), gold, tin, platinum and platinum metals, a little magnetite and limonite, small garnets (?), and occasionally a few flat sandstone pebbles, the largest hitherto seen measuring one foot by eight inches by two inches. The quartz grains are white and opaque, with a large sprinkling of pieces of rock crystal; a few show traces of crystalline facets, but most of them are well rounded. As a rule, the black sand rests upon, and at the side passes imperceptibly into, a white sand, consisting chiefly of fine and well-rounded quartz grains; generally it also overlies, and at some places, at the sides, butts against a rock locally known as the "black rock," which latter is a consolidated sand, ferruginous and peaty, and in places quite compact. The rock is said to carry gold in places, and is considered to be bedrock; but although it is a boundary rock for the deposits which have been discovered, it is not bedrock in the true sense of the term. If slate similar to that which occurs at Bullock creek, or sandstone identical with the Evans river sandstone, be touched, it is useless to continue sinking in the hope of discovering a deposit of black sand, but the "black rock" belongs to a formation distinct from both sandstone and slate, and although in places it may rest directly upon bedrock, it is possible that in other parts auriferous black sand may be found beneath it.

The gold, which has a value up to £4 2s 3d per ounce, is very fine, and the samples I examined were free from rust; most of the specks are somewhat 'shotty,' and should be readily saved on copper plates, but there is a certain proportion which is scaly and liable to be lost. On most of the claims the ordinary box, followed by copper plates and blankets, is used for collecting the gold, and it seemed to me that in most cases the quantity of water flowing over the plates was excessive, and the plates themselves were not kept sufficiently bright to save the float gold; when the last copper plate is found to be thickly covered with amalgam, there cannot be much doubt that gold is being lost. The miners say that if they attempt to save all the gold a smaller quantity of pay dirt will be put through, and that they prefer the greater output with the attendant loss rather than a smaller quantity treated with a more perfect saving of the metal.

With the gold are associated platinum and platheid metals. The platinum is of a steel gray color, and occurs chiefly as minute flat specks with a metallic luster, and of a more or less circular longitudinal section, occasionally turned up at the edges.

A RESIDENT of Lander county furnishes the Carson *Tribune* with the following information on the situation in Austin: "Although Austin is by no means a lively camp, there are but few idle people to be seen. The Austin Mining Company has about 100 men employed in the mine and mill. The main shaft is down 750 feet, good ore being found all through the ledge, and from 40 to 50 tons being extracted every day, the majority being worked by the concentrating process and the higher grade stowed away for shipment."

NEGOTIATIONS are pending at Victoria, B. C., for bonding the lands on the northern end of Gabriola island to a New York syndicate. They have a representative inspecting the coal treasures of the district. The New Vancouver Coal Company owns several thousand acres in the southern and central portions of the island, which is situated about three miles from Nanaimo, and the people are also said to be inquiring as to iron deposits at Sooke, near Victoria, which have been reported on most favorably by eminent engineers.

THERE are probably 1000 men at work in and around the various mining camps of Big Bug, Chaparral and Lynx Creek districts, which are all within 20 miles of Prescott, Arizona. Seventy-five men are on the payroll of the Henrietta mine alone, and nearly as many more are employed in various capacities in the camp. Nearly an equal number is employed at John S. Jones' camp and a large number more at the McCabe mine.

The Hurleton District, Butte County.

Abridged from Article in *Forbestown Mining New Era*.

Hurleton is situated about 12 miles east of Oroville, and 10 miles west of Forbestown, at an altitude of about 1200 feet, and is on what is known as the Oroville, Forbestown and La Porte road. It was established by its present owner, Smith H. Hurles, about 40 years ago, and has ever been a favorite stopping place for those traveling over the road. It contains a postoffice, store, hotel, and is the place for changing horses by the Oroville & Forbestown Stage Company. It is below the snow belt, and has as healthy and agreeable climate as can be found in the State.

It is also in a very promising mining section, being surrounded by quartz ledges, many of which are known to be valuable, which in time cannot fail to make it an important place. In earlier days considerable gold was taken from creeks and ravines in the immediate vicinity, but these are now about exhausted and the attention of the miner has been turned to quartz.

The first place recently visited by us was the Phoenix quartz mine, of which Capt. Rodda is superintendent. Being Sunday, no work was going on in the mine, but we found Mr. Rodda at the mill, which was also shut down for a few hours to clean up and make some slight repairs. The superintendent reported everything running smoothly and the results satisfactory. The mill now used is known as the Bryan roller mill and does the work very well. But the superintendent informed us that the mill was not intended by the company to be a permanent fixture, but more for the purpose of prospecting, and that in the near future a stamp mill would be built. This mill is so situated that ore from three ledges which the company own can be worked in it. At present they are running on ore from the Phoenix ledge, which has to be hauled about a mile; but the site for the new mill is much nearer the mine. Capt. Rodda is an old and experienced miner, having worked in several camps in California and also in Mexico, and speaks in the highest terms of the mines he has charge of, and also of several other ledges in the vicinity upon which development has been done. The rock, as a rule, does not carry as much sulphurets as that around Forbestown, the gold being more free.

Just above the Phoenix mine is the Resumption mine, owned by McMillian and son. This is a good-sized ledge and some very good ore has been taken from it. The owners are talking of putting up an arrastra to fully develop the same.

We also visited the Dutch Ravine mine, owned by H. P. Stow of Forbestown. Here work was also suspended for the day, but we met the superintendent, Mr. Hampton, and from him we learned that 12 men were employed; that the shaft was down 160 feet; that the workmen were now engaged in driving a tunnel to tap the ledge; that they were making about 80 feet per month, and that about 300 feet would have to be run before the ledge would be reached. Mr. Stow has great faith in this mine, as is evidenced by the work he is doing to open it. The shaft is well timbered, and when the ledge is reached it can be used as a hoist. The mill, if one is built, will be below the shaft and be driven by water power. Everybody in the neighborhood is looking forward to the tapping of the ledge as a period that will awaken a new era in mining in that vicinity.

We visited a recently discovered ledge known as the Hurleton King, and owned by W. W. McMillian, Jr. This ledge commences to show itself near the main road, a short distance above the Hurleton hotel, and can be traced by croppings for nearly a mile. Its course is nearly north and south, and at a point where a small opening has been made it shows a width of six feet, and in several pieces of rock carelessly picked up from that which had been thrown out, we discovered free gold. The rock carries considerable sulphurets and has every appearance of being rich. The beauty of it is that it can be easily and cheaply worked. There being a splendid site for a mill under the Forbestown ditch, water can be used and returned to the ditch without waste, and the ledge can be tapped within a few feet of the mill.

Mr. Hurles also has a fine looking ledge on his land, about a quarter of a mile from the hotel, which assays show to be valuable. This, as is the case of the Hurleton King, is under the Forbestown ditch, and for a mill site has the same advantages. Mr. Hurles has had several experts examine his mine and there are prospects of a sale or bond in the near future.

We also visited several of the undeveloped ledges and thought we saw a bright future in store for the district, but a great deal depends upon the success of Mr. Stow's operation in Dutch ravine. Should this prove a success and a paying mine be developed, there will be no lack of capital for other operations. The country around Hurleton is one network of quartz, and we predict that some day one of the largest and most prosperous mining camps in the State will be found here.

Scientific Progress.

The Seven Images of the Human Eye.

It is well known that in the human eye, besides the refracted image, which serves the purposes of vision, there are formed three reflected images known under the name of "Purkinje's Images." M. Tcherning has discovered three additional ones, so that the total number is brought up to seven.

In its passage into the interior of the eye each ray of light has to pass through the cornea, the aqueous humor, the crystalline lens, and the vitreous humor, before finally arriving at the retina. At the surface of each of these constituents the ray is liable to be partially reflected, thus giving rise to four reflected images. These were all seen and described by Purkinje at the beginning of the century, but only three were observed by Helmholtz and others. These three, says a writer in *Nature*, can be easily observed by two persons on holding a lighted match between their eyes, and moving it about so that the reflections seem to come from the pupil. One of them, that reflected by the front of the cornea, is much brighter than the two others, which are formed by the front surfaces of the crystalline and the vitreous humor, respectively. The fourth image is due to reflection from the posterior surface of the cornea. It may be discovered by careful observation of the brightest image by means of a magnifying glass. As it approaches the border of the pupil, and especially as it passes on to the iris, it is seen to be accompanied by a small, pale, but well-defined image, which always lies between the first image and the center of the pupil, the distance between them decreasing as they move toward the center, where they finally coincide. By means of the ophthalmometer—an instrument consisting of three incandescent lamps and a telescope arranged on an arc of 86 cm. radius—it was found possible to measure the radii of curvature of all the reflecting surfaces. The foci of the two reflecting surfaces of the cornea were found to coincide, a fact which accounts for the coincidence of the two corresponding images at the center of the pupil, and for Helmholtz's failure of finding the fainter one.

It is evident that since the light reflected from the successive surfaces does not fall upon the retina, it is lost for visual purposes. But a comparison of the percentages of loss in the case of the eye, and in that of a simple lens, tells greatly in favor of the former as an optical instrument. In the eye the percentage of useful light is 97, in a simple lens 92, and in a compound optical instrument correspondingly less. But the light reflected by any one of the internal surfaces is also liable to be reflected back into the eye or the optical instrument, with the effect of super-imposing a more or less faint patch of light upon the image on the retina. This is termed the noxious light (*lumiere nuisible*) by M. Tcherning. In a simple lens this amounts to $\frac{1}{2}$ per cent, while in the eye it is as low as 0.002 per cent. But faint as it is, it is capable of giving rise to two light impressions due to double reflection, one, at least, of which has been actually observed in the human eye. "The easiest way of observing it," says M. Tcherning, "is to look straight forward in a dark room, holding a lighted candle in the hand, about 20 cm. from the line of vision. On moving the candle gently from side to side, a pale image of the flame is seen on the opposite side of the line of vision, distinct enough to show that it is inverted; it moves symmetrically to the candle with respect to the line of vision. The rays which form this image have undergone, besides several refractions, two reflections, one at the posterior surface of the crystalline and another at the front surface of the cornea." Another image was expected to be formed by a similar reflection

at the anterior surface of the crystalline. It was found in an artificial eye, but not in the human sense-organ. However, an easy calculation of the optical system of the eye explains this circumstance. The focus of the reflected rays is very near the crystalline lens itself, so that they must be much dispersed by the time they reach the retina. To enable the image to be formed on the retina, the object would have to lie between the cornea and the crystalline, but on attempting to form a luminous point at that place by optical means, it is found that the "useful rays" fill the eye to such an extent as to render everything else invisible.

It is found that different eyes differ in their capacity of seeing the first of the two additional subjective images. Short-sighted people find it very indistinct unless the candle is held close to the eye, or convex glasses are used. As the maker of optical instruments utilizes the accessory images for testing the degree of polish and the accurate centering of the lenses, so the physician is enabled to make valuable inferences from them as to the structure and condition of the eye he is examining; and the additional images discovered by M. Tcherning appear to be of considerable physiological importance.

The Influence of the Mind Upon the Body.

J. E. Wenman, M. D., in the *Eclectic Medical Journal*, says: In Mr. Warburton's work on Egypt he describes his experience with a famous magician in that country. He, being sent for, came to Mr. Warburton's hotel to give him an exhibition of his skill. The magician calls a boy from the street, and makes a mysterious mark upon the palm of his hand, requesting him to look steadfastly upon the mark. This the boy did for ten minutes without any effect. The magician called another boy, and repeated the same thing. This boy, being susceptible to the influence, was soon in a semi-mesmeric condition, the object of the mysterious mark on the palm of the boy's hand being the means of putting the boy in a passive condition. The magician now requested Mr. Warburton to call up whom he wished, and stated the boy would see him. Mr. Warburton called for the late Lord Derby. The boy instantly called out: "Here he is. I see an old man, with spectacles, lying on a couch, having on a long black robe." Mr. Warburton next called for the late Lord Nelson. The boy said: "Here he is. I see a soldier with one arm." After calling for several others, the boy minutely described them, to the astonishment of Mr. Warburton and his friends.

Now the trick consisted in getting the boy to suspend his thinking faculties, so that he would become in a semi-mesmeric condition, and thus be in sympathy with the mind of Mr. Warburton when he called for the different individuals. The boy saw in a kind of vision the very picture that was passing through Mr. Warburton's mind when he called for these individuals. This is a high development of a clairvoyant condition.

Transparency of the Ether.

A noticeable point in connection with the free transmission of light through space is that, so far as the ether itself is concerned all colors are, in the opinion of astronomers equally unaffected by absorption, says the *Optician*. The fact is accounted for, presumably, by the enormous frequency of the simple vibrations of the etherial elements, rendering such vibrations alike incomparable with those of either red or blue light. If it be assumed that the ether is pervaded by some definite minimum of heat motion, it is, however, necessary to admit the existence in it of an absorption band. And it is impossible that there can be sensible heat in the ether unaccompanied by absorption of an equally sensible character.

THE GRIFFIN MILL

The Only Perfect Pulverizer

OF
QUARTZ,
GOLD
OR SILVER
ORES,
PLUMBAGO,
PORTLAND
CEMENT,
OF
PHOSPHATE
ROCK,
FOUNDRY
FACINGS,
And All Other
Refractory
Substances.

Will work either wet or dry, and deliver a finished product. Capacity, 3 to 4 tons per hour on Phosphate Rock, $1\frac{1}{2}$ to 2 tons per hour on Portland Cement, Quartz or Ores, depending on hardness of material to be pulverized and fineness of product. Grinds from 30 to 250 Mesh with equal facility.

NO JOURNALS IN GRINDING CHAMBER. BALL RIGID ON SHAFT HAVING DIRECT POSITIVE ACTION ON MATERIAL. MINIMUM POWER PRODUCES MAXIMUM AMOUNT OF PRODUCT. IT IS ABSOLUTELY GUARANTEED IN EVERY RESPECT, BOTH AS TO CONSTRUCTION AND CAPACITY. FIRST COST, WEAR, AND OPERATING EXPENSE MUCH LESS THAN STAMP MILLS. LARGE NUMBER OF MILLS IN USE ON DIFFERENT MATERIALS WITH POSITIVE SUCCESS IN EVERY INSTANCE.

Correspondence solicited, and illustrated descriptive pamphlet furnished on application to

Mechanical Progress.

Superheated Steam in Small Motors.

Some remarkable results have recently been obtained in a trial of a Serpollet motor, conducted by M. Segnin. These results are particularly interesting, as they show the economical advantages of superheated steam in a noteworthy manner. The motor, as described by *Engineering*, England, as having a single horizontal cylinder, 5.1-inch diameter by 5.1-inch stroke. The cutoff was fixed at 66 per cent of the stroke; the admission pressure was 58 pounds per square inch, and the revolutions 248 per minute. The brake horse power on a four hours trial averaged 4.57-horse power, and the steam consumption was but 29.87 pounds per brake horse power per hour. Comparing this result with those obtained with somewhat similar-sized motors at the Plymouth trials of the Royal Agricultural Society, England, it will be found that the best engine there, a compound one, took 35.75 pounds of steam per indicated horse power, whilst the best of the single-cylinder engines took 57.75 pounds of steam per indicated horse power. Practically the whole of the advantage shown by the Serpollet motor must, we think, be credited to the boiler, which supplies superheated steam. This boiler consists of a stout tube flattened so as to deform the passage through into a narrow slit. This tube is coiled, and has one end connected with a feed pump, and the other with the engine to be driven. The boiler used in the above tests had a heating surface of 26.8 square feet, and the grate area was 2.9 square feet. The steam, though showing on the gauge a pressure of 58 pounds per square inch only, had a temperature of 1009° F. on issuing from the coil, which had fallen to 572° F. at the steam chest. The temperature of saturated steam at 58-pound pressure is about 306° F., so as used in the engine the steam was superheated by some 266°. The output of steam was just 4.9 pounds per square foot of heating surface per hour. The fuel used was briquettes, having a heating value as tested in a calorimeter of 8.28 pounds of water evaporated from and at 212° F. per pound of fuel, and as used in the boiler the efficiency was 67.3 per cent.

Improved Steam Pipes.

To obviate the risk of careless brazing, and enable the thickness of sheet copper forming the pipe to be reduced to a minimum, at the same time that full advantage of wire winding is secured, a patented system of manufacturing steam pipes is being experimented with by a west of Scotland firm, says the *Scientific American*. It forms even a closer analogy to the wire gun than the present system of wire winding, and consists of using copper of the thinnest practical gauge, to form the interior or core of the pipe, the body of the pipe proper being composed of steel wire wound closely round the core, the interstices between the coils being filled in solid with copper by a patented system of copper electro-deposition. Pending this and other possible improvements on copper pipes, one result of past experience with these is to give an impetus to the use of lap-welded wrought-iron pipes. In the new Connard steamers, Campania and Lucania, the main steam pipes are of this type, and experience with these so far hears out the contention of some engineers that for modern high pressures they are, on the whole, the best that can be used.

Large Pulleys.

It is a mistake to use pulleys very small in diameter when large ones can be used just as well. It is true that small pulleys do not cost as much as large ones, but when that is said, all has been said that can be said in favor of the use of small pulleys;

while in favor of large pulleys as substitutes for the small ones, it can be said they save money during their entire lifetime, and therefore probably save many times the difference in first cost.

A six-inch belt on a pair of twelve-inch pulleys may be able, says *Dixie*, to do just the work required without slipping or extraordinary strain, and in so doing will, with care, perhaps live the ordinary lifetime of such a belt, yielding at last from sheer exhaustion; whereas if the same belt were run on 24-inch pulleys instead, it is reasonable to suppose it would last twice as long, with the same care, because the constant strain would be only half so great. But then with 24-inch pulley it would not be necessary to use six-inch belts, as a belt four inches wide would do the work easier than a six-inch or twelve-inch pulleys, and would last longer if of equally good quality. Either way, the larger pulleys are, in the end, by far the most profitable and should always be selected in preference to small ones if other conditions will permit it.

Manufacture of Bronze Powder.

Nearly a hundred establishments are engaged in the manufacture of bronze powder in and near the cities of Furth and Nuremberg, Germany. The article is composed of copper, tin, zinc and antimony, melted in proper proportions, and cast first into rods of half an inch in diameter and about three feet long, these rods being rolled until about two inches wide and then cut into suitable lengths for handling. The pieces go to the hammers, where they are beaten into a very small fraction of their former thickness and are then taken to a sulphuric acid bath, where each sheet is washed to remove all impurities, rust and dirt. After being thoroughly dried, the sheets are again hammered by steam hammers until no further reduction is possible, there being a limit to which machinery can be used.

Up to this stage the treatment which the metal receives, whether intended for powder or metal leaf, is identical; but now the process changes. If designed for metal leaf, the further heating is done by hand; but if for bronze powder, the sheets go to the shears, where they are cut up into small particles and become known as clippings. These are now ready for the stamp mills, which are run in batteries, enabling one man to run or attend 50 or more. When sufficiently pulverized, the powder is sifted in a special manner, the heavier and better qualities going to one receptacle and the inferior grades to another.—*American Paper Trade*.

Cutting Mica.

At the glass house the mica is put into shape for shipment. The blocks vary greatly in size. One from the Wiseman mine, near Spruce Pine, is reported to have been six feet long by three feet wide. Pieces a yard in diameter have been obtained at the Ray mine, in Yancey county, and similarly large plates have been found in Siberia, but these are exceptional. The average block is little larger than the page of a magazine, and is generally less than six inches in thickness. It separates very readily into sheets parallel to the base of the prism. It is estimated that this cleavage may be carried so far that it would take three hundred thousand of the mica plates to make an inch. It is needless to say, however, that such a thickness is not suitable for service in stoves and furnaces. The mica is generally split into plates varying from about one-eighth to one-sixty-fourth of an inch in thickness. In preparing these plates for market, the first step is to cut them into suitable sizes. Women are frequently employed in this work, and do it as well as, if not better than, the men. The cutter sits on a special bench which is provided with a huge pair of shears, one leg of which is firmly set to the bench itself,

while the movable leg is within convenient grasp. It is requisite that the shears shall be sharp and true, for otherwise they will tear the mica.

The patterns according to which the mica is cut are arranged in a case near at hand. They are made of tin, wood, or pasteboard, according to the preference of the establishment. Generally they are simple rectangles, varying in size from about four square inches to eighty.—C. H. Henderson, in the *Popular Science Monthly*.

Langbein's Splendid Book on the Electro-Deposition of Metals.

A New Revised and Enlarged Edition.

JUST READY.

A COMPLETE TREATISE ON

The Electro-Deposition of Metals

Comprising Electro-Plating and Galvanoplastic Operations, the Deposition of Metals by the Contact and Immersion Processes, the Coloring of Metals, the Methods of Grinding and Polishing, as well as Descriptions of the Electric Elements, Dynamo-Electric Machines, Thermopiles, and of the Materials and Processes used in every Department of the Art. Translated from the German of Dr. George Langbein, Proprietor of a Manufactory for Chemical Products, Machines, Apparatus and Utensils for Electroplaters, and of an Electroplating Establishment, in Leipzig. With additions by William T. Brandt, Editor of the "Electro-Chemical Receipt Book." Second edition, revised and enlarged. Illustrated by one hundred and thirty-eight engravings, in one volume, 8vo, XXVIII and 430 pages. (463 pages.)

Price \$4.00 free of postage to any address in the world.

A circular of 6 pages quarto, giving the full Table of Contents of this splendid Book, with specimens of the illustrations, will be sent free of postage to any one in any part of the world who will furnish us with his address.

Our New and Enlarged Catalogue of Practical and Scientific Books, 88 pages, 8vo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish us with his address.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$3.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.
The work is divided into four parts: Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Useful Information.

Famous Meteoric Stones.

A meteoric stone, which is described by Pliny as being as large as a wagon, fell near Agopotami, in Asia Minor, in 467 B. C. About A. D. 1500 a stone weighing 1400 pounds fell in Mexico, and is now in the Smithsonian Institution at Washington. The largest meteoric masses on record were heard of first by Captain Ross, the Arctic explorer, through some Esquimaux. These lay on the west coast of Greenland, and were subsequently found by the Swedish exploring party of 1870. One of them, now in the Royal Museum of Stockholm, weighs over 50,000 pounds, and is the largest specimen known.

Two remarkable meteorites have fallen in Iowa, says the *San Francisco Call*, within the past 20 years. February 12, 1875, an exceedingly brilliant meteor, in the form of an elongated horseshoe, was seen throughout a region of at least 400 miles in length and 250 in breadth, lying in Missouri and Iowa. It is described as "without a tail, but having a flowing jacket of flame. Detonations were heard so violent as to shake the earth, and to jar the windows like the shock of an earthquake," as it fell about 10:30 P. M., a few miles east of Marengo, Ia. The ground for the space of some seven miles in length by two to four miles in breadth was strewn with fragments of this meteor, varying in weight from a few ounces to 74 pounds.

On May 10, 1879, a large and extraordinary luminous meteor exploded with terrific noise, followed at slight intervals with less violent detonations, and struck the earth in the edge of a ravine near Estherville, Emmet county, Ia., penetrating to a depth of 14 feet. Within two miles other fragments were found, one of which weighed 170 pounds and another 32 pounds. The principal mass weighed 400 pounds. All the discovered parts aggregated about 640 pounds. The one of 170 pounds is now in the cabinet of the State University of Minnesota. The composition of this aerolite is peculiar in many respects; but, as in nearly all aerolites, there is a considerable proportion of iron and nickel.

It is generally held that meteors at one time or another formed integral parts of a comet. The meteor enters the earth's atmosphere from without with a velocity relative to the earth that is comparable with the earth's velocity in its orbit, which is 19 miles per second. By the resistance it meets in penetrating the air, the light and the other phenomenon of the luminous train are produced. Many small meteorites are undoubtedly consumed by this fire, caused by friction, before they reach the earth's surface.

Florida Ants.

There are more ants to the square mile in Florida, says the *Savannah News*, than in any other country in the world. There are ants which will measure more than half an inch in length, and then there are ants so small that they can scarcely be seen to move with the unaided eye. There are red ants and black ants and troublesome ants. But as bad as they are, I have never heard of them eating out the seat of a man's trousers, as a missionary, the Rev. Mr. Wilson, once told the writer he saw the army ants do in India while the man was sitting on the earth for a few minutes beside him. But the Florida ants will take out lettuce and other minute seeds from the soil in which they are planted and actually destroy the seeds. They will suck the life out of acres of young cucumbers and melon plants, niproot strawberry plants or cover the buds with earth to such an extent as to kill them. They will get into pie, pickle, sauce, syrup, sugar; on meat, in hash; will riddle a cake or fill a loaf of baker's bread

till it is worthless. All remedies failing, I took to baiting them near their nests with slices of meat, bones, apple and pear parings, and when I had from 50,000 to 100,000 out, I would turn a kettle of boiling water on them. I have killed during the past week over a million in the space of a quarter-acre lot, and I have almost wiped them out. I had to do this to secure any lettuce plants, and many inobservant farmers complain of seedsmen when they should attribute their troubles to insects.

Boiling Water Not Always Hot.

"Cold boiling water, indeed! Boiling water is the hottest kind of thing. Don't I know? Haven't I scalded my fingers more than once with water from the teakettle?"

James is right, and yet he is wrong, remarks the *New Orleans Times-Democrat*. Boiling water is not always very hot water, in spite of his painful experience. This is the way it happens:

When the water boils, ordinarily it is because great heat has separated the tiny particles of the water, forcing upward and outward in lively bubbles the air which is contained in them. This is done in spite of the downward pressure of the atmosphere. After the water has become hot enough to boil, it can get no hotter, because the air escapes as fast as it is sufficiently heated to do so.

There are places on the earth where the pressure of the atmosphere upon the water is so slight that it requires but little heat to push apart the particles and set free the air bubbles which are confined in the water, so it begins to boil before it becomes very hot. It ought hardly to be called cold water, perhaps, but it is certainly far from being as hot as ordinary boiling water. This state of things is found on all high mountain tops, as the atmosphere grows weaker and its pressure less as one ascends.

A gentleman traveling at a great elevation in the Andes mountains put some potatoes in a pot of water over a hot fire. The water began to boil almost immediately, but the potatoes did not cook. All the afternoon and all night the water bubbled and boiled, but still the potatoes were not cooked. The boiling water was not hot enough.

Snails Live Indefinitely.

The Smithsonian Institution has hit upon something extraordinary in snails, says the *Washington correspondent of the Providence Journal*. The creatures may be slow, but they hold the record over all other animals for prolonged vitality under adverse conditions. Stories of toads dug out of rocks, in which they have been imprisoned for ages, are apocryphal; but recent discovery has established the credit of this humble mollusk as number one in tenacity of life. Only the other day a specimen from an island off the coast of California, inclosed in a drawer with part of the molluscan collection, was found to be alive. It had had no food or water for more than six years. When placed in a box with moist earth it protruded its foot and began to move about, and seemed to be as well as ever. Some time ago a few snails of a different species, gathered in Mexico, reached the Smithsonian Institution and were placed in a box. They remained undisturbed for two years and three months, at the end of which time they were put into a glass jar with some chickweed and a small quantity of tepid water. Pretty soon they waked up and appeared quite active.

How Old Is the Human Race?

The fullest answer that science can yet give to the three most interesting questions, perhaps, ever asked in the world is explained in an interesting article in the *December Forum*, by Daniel G. Brinton, the ethnologist. These questions are: "When did the

first man appear?" "By what process did he appear?" and "Where did he appear?" Summing up all that geologists and anthropologists know, he appeared certainly 50,000 years ago, and it may be as many as 200,000 years ago. The evidences of his existence which date back 50,000 years are unmistakable. By what process he came into being, science has no definite answer. If it refuse to accept the doctrine of specific creation, it must refuse also, for lack of complete evidence, to accept the doctrine of gradual evolution—the old Darwinian doctrine. Dr. Brinton thinks the theory of "evolution by a leap" is as good as any other theory. According to this, man sprung from some high order of mammal, the great tree-ape, perhaps, by a freak, just as men of genius are freaks, and as all the vegetable and animal kingdom show freaks. As to where man first appeared, it is beyond doubt that his earliest home was in Southern Europe, or Asia, or North Africa. No earlier traces of him have been found than those found in the area that is now England, France and Spain.

Plaster of Paris.

The method of testing the quality of plaster of Paris is by taking a small pinch of the powder between the thumb and finger and gently rubbing it; if small particles of grit are felt, it indicates that parts of the plaster have already absorbed water, and it is therefore unfit for use. The same test may be observed by taking a pinch of the powder again and placing the fingers under water, and then rubbing in the same way as before. If, however, in both of these tests no grit is felt, and under water a thin, creamy substance is formed, which is easily rubbed off the fingers, the plaster is in a proper condition for use. Where plaster has been kept for a long time, or where it is gritty, its condition can be very greatly improved. It may be redried by putting it in a metal dish, such as a pie plate or iron pot, and placing in an oven of a hot fire or over a gas jet. As soon as it becomes heated it will be observed that a process identical with boiling water is taking place. When the ebullition has entirely ceased, the powder is freshly kiln-dried. If the method of testing is again resorted to, it will be found that the gritty appearance and feeling will have disappeared, in a very large measure, leaving only the fine, dry powder ready for use. If there are any lumps remaining, they may be removed by the use of a sieve. From what has been already said, it will need be but a reminder that the plaster of Paris must always be kept in a hermetically sealed jar or in a very dry place.—*Charlotte Medical Journal*.

Electricity.

To Utilize the Bosphorus.

There is a certain Greek engineer, now resident in Europe, who ought to have been an American, for he is the author of just the kind of a scheme that, in the matter of boldness and picturesqueness, the world at large look to Yankee land to originate. At various points on the Bosphorus the current from the Black sea in the Mediterranean has prodigious force, and it is now proposed to harness some of this waste power for the lighting of the whole city of Constantinople and a considerable length of the adjacent coast by electricity. The way in which the inventor intends to turn the ocean currents in account is to erect three very powerful dynamo machines upon the three points of the Bosphorus where the current has the greatest force, and, so far as can at present be learned, the project seems to be practicable and realizable. It is stated that a company of capitalists has been formed, the necessary funds subscribed and application for concession addressed to the Turkish Government. It is understood that the Gov-

ernment has taken the project into consideration and nominated a commission to report on it.

Winding and Setting Tower Clocks.

The winding and setting of a good-sized tower clock of the time-honored pattern is by no means a small job, inasmuch as the raising of a ton or so of dead weight to the top of a high tower once a week is necessarily a work of time as well as labor. All this drudgery, it appears, is henceforth to be performed by the ubiquitous electric motor. A new clock recently placed in a building of the Waterbury Clock Co., Waterbury, Conn., is not more than one-fourth the weight of a tower clock of the ordinary type, having dials of equal diameter, and the whole machinery is operated by electric motors supplied with current from a sal-ammoniac battery of ten cells, which will run for a year or two without renewal. The great saving in actual power required to propel the clock largely results from the fact that the electric force is applied directly to the point where needed, without the intervention of the complex mechanism essential in weight clocks of the ordinary type.

An Inexpensive Electrical Machine.

Take a glass, expose it to the fire, so that it shall be perfectly dry, and place it upside down upon a table. Afterward, take a tray perfectly dry and place it upon the glass in such a way that it shall preserve its equilibrium. Finally, take a sheet of paper slightly smaller than the tray, heat it and rub it rapidly with a brush, and it will become quickly electrified. Then place it upon the tray. An electrical machine will thus have been constructed without any expense. If the finger be brought near the tray a spark will appear. This spark will be so much the brighter, and the series of sparks will be so much the longer, in proportion as the glass and trays are drier. If, while the sparks are being drawn from the tray, the room in which the experiment is performed is darkened, these sparks will appear extremely brilliant.—*Boston Journal of Commerce*.

Making Ozone.

An attempt is being made in London to produce ozone on such a scale that it will be available for innumerable hygienic and commercial purposes. The apparatus used is electrical, the ozonizer consisting of a number of serrated strips formed up into grids and separated from each other by plates of glass. On connecting these grids with opposite terminals of a high potential alternating current, what is called a "brush discharge" takes place on to the glass from the points of the serrations, and characteristic smell of ozone is quickly apparent. To make the ozone in still greater volume, a large number of these plates are so arranged in a suitable case that when the discharge is established, a current of air is passed through the apparatus, whence it emerges heavily charged with ozone. Before the air is passed into the ozonizer, it is filtered, cooled and dried, so that its purity is insured.

The Poor Man's Light.

Electricity will eventually provide the poor man's light, Mr. Peerce is reported to have said, and we think it a reasonable prophecy, says *Invention*. The management and control of the electric motor is simple; its service is in direct and immediate command; it requires no fuel; in economy of space occupied it has no competitor, and, in some cases, where needed for intermittent use, power can be furnished at one-tenth to one-fifth the cost of steam. An American contemporary points out that the electric motor has found its way into plumbing, metal spinning and machine shops in New York, and considers that there can be no grave doubt as to its more general adoption.

Hunting Lost Mines.

Hunting for lost mines seems to be a prominent industry at present. According to stories told by some old timers, one of these fabulously rich properties is supposed to exist somewhere within a few miles of Prescott, to the southwest of the town. The story, as told to the *Journal-Miner*, is to the effect that away back in the early 70's, "when Indians were had" in the country, a detachment of troops was sent out to camp on the old Indian trail running from Skull valley to Lynx creek, to guard the trail and to intercept a band of Indians that was expected to pass over it. The troops remained in camp for several days, and broke the monotony of camp life by prospecting for gold in the immediate vicinity. On their return to the post, it is said, that they brought in a lot of gold, which they obtained by grinding the ore between rocks. An officer was about to accompany some of the troops back to the spot for the purpose of locating some claims, when urgent marching orders were issued calling him with his troops out after the hostiles. When the campaign was over, he and his command were stationed at another post and never returned to Whipple again, although he wrote that he intended to again visit this section and hunt for the ledge from which his soldiers obtained this fabulously rich ore. Of course, intending to take advantage of their own find, they naturally kept it as quiet as possible, and but few of the then residents of the country knew of it. In later years, or about six or seven years ago, parties hearing of these circumstances went out and made a desultory investigation of a portion of the mountains in the neighborhood from which the ore was supposed to have been obtained, but nothing like a thorough prospecting of the country was had. There are a number of ledges in that section of the country, some of which have been partially prospected, but as yet nothing of any value has ever been obtained in any of them. A fortune may yet await the lucky discoverer of the ledge from which the soldiers obtained their rich ores.

Why Big Salaries Are Paid.

To the untechnical outsider the huge salaries paid nowadays by gold mining companies for efficient mine managers and consulting engineers must frequently appear unjustified, says the *London Mining Journal*. There is, however, no department of human activity in which the "two ways of doing it" produce more striking differences than the auriferous quartz treating industry. One has only to compare the cost of mining and millage at mines where adequate technical supervision has secured efficient machinery and proper methods, with others where a lower standard of skill is manifested, to fully appreciate this. Some of the gold mines in the United States are paying dividends upon ore ranging as low as 4 dwts. to the ton. The Treadwell mine, on Douglas Island, Alaska, is said to obtain gold more cheaply than any other in the world. It is very well situated for cheap working, as the mill is driven by water power, the mine is dry, and the ore has only to be quarried. Ships also can discharge within 400 yards of the mine. However, the ore is only 8 dwts. to the ton, and the profits obtained are mainly due to the employment of every possible labor-saving appliance. There are 240 heads of stamps at work, and the ore is extracted and milled at a cost of only 6s. per ton. Some of the mines under British management in Australia and elsewhere are not, however, inferior to the best-equipped American mines.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breakage of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Reconditioning; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Course Metal; Assay of Roasted Ore for Solubility; To Assay a Specimen; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is replaced by new matter. Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner.....\$550, f. o. b.
 " " Improved Belt Frue Vanner..... 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

GLADSTONE MINING COMPANY, O. J. Clark, M. E. Gen'l Supt. FRENCH GULCH, Shasta Co., Cal., Dec. 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—Dear Sirs: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

H. J. SUMMERHAYES, Successor to Adams & Carter, Agent for the FRUE ORE CONCENTRATOR.
 No. 182 Market Street, - - San Francisco, Cal.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable. Price \$575 f. o. b. Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allotted to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

GEO. E. WOODBURY, Manufacturer, 213 to 219 First Street, San Francisco, Cal.

PATENTED
Aug. 19, 1890.

Eureka Tellurium Gold Mining Company, Redding, Cal., July 21, 1893.—Mr. Geo. E. Woodbury, 213 First St., San Francisco, Cal.—Dear Sir: We take pleasure in stating to you that the two Ore Concentrators purchased from you last April are giving perfect satisfaction. They are simple, durable and effective, and we hereby conscientiously recommend the "Woodbury" pattern to all intending purchasers of Ore Concentrators. Yours truly,

[Signed] EUREKA TELLURIUM GOLD MINING CO., by GEO. O. JONES, Secretary.

Electrical Engineering in all its branches, and Construction Work undertaken.
PACIFIC ELECTRICAL STORAGE CO., 118 & 120 Pine Street, San Francisco, Cal.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs in the shaft. SPECIAL CONSTRUCTION OF STEEL only one-eighth part the weight of the old pump. Works with 10 per cent less power. First outlay one-third less. Suitable to any underly or downright shaft. Occupies less space in the shaft. Has been tested a year and proved to work satisfactorily in every respect. GLAND OF STUFFING-BOX TIGHTENED AND OIL LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING OR BUCKET PUMP.

Bucket, clack and clack-sealing changed under water. Bucket lasts six times as long as the old bucket, often saving expense of putting down another pump, especially in jack-head pumps, where bucket and clack cannot be changed under water. Special attention is called to the self-tightening stuffing-box and new bucket which obviates the expense and delay of frequently dropping extra pumps.

Scientific Press

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S. F.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

A NEW GRIFFIN MILL.—*Ledger*, March 29: Superintendent Hale of the Keystone has just ordered a Griffin mill which will be set up on that property in a few days. It is to be put in by the agents at their expense, to be paid for by the company, provided it comes up to their guarantee in efficiency.

Messrs. Thomas and Belshaw went up to the Gwynn mine Thursday from San Francisco, and this morning Messrs. Downe, Voorhies and Barney drove over from Sutter Creek and met them on the ground. Their business was to survey the property with relation to locating the shafts, buildings, etc.

The contractors at the Bay State mine are making good headway in the shaft. They have now reached a depth of 480 feet. The ground is in excellent condition for sinking, and strainers of quartz coming from the ledge are now being passed through. At the present rate of sinking, crosscutting to the ore body will be commenced by the first of May.

The Mayflower and the South Mayflower properties, near Amador, have added to their possessions the Amador mine, and they now own from Amador creek to Ranchera creek. Upon these properties there are five shafts, two of which are being sunk and two more in which work will be commenced in a few days. Several tunnels have been run into the hill and have been prospected much to the satisfaction of N. W. Crocker, the superintendent of the various properties. They are running ten stamps now, but as soon as the mill is repaired, twenty more will be added. Fifty men are employed upon the work now, but as development progress, many more will be put on.

Butte.

AT CHEROKEE.—*Oroville Mercury*: T. L. Vinton, the merchant of Cherokee, paid us a call to-day. In response to the query of "How is Cherokee?" he replied: "There is still a large quantity of gold being taken out of the Cherokee mine every day. It will average to my knowledge \$100 per day right along, and a great deal more is extracted by companies that I know nothing of. The men work the ground on percentage, paying for the privilege. The idea that Cherokee is entirely dead is a mistaken one. This amount of money coming from the ground every day keeps many families in prosperous circumstances."

Mr. Vinton is one of the firm believers in the great wealth of the Spring Valley mine and the future importance of Cherokee as a mining town. He is confident that within a few years, as soon as litigation is settled, the mine will be reopened by the drift system, and that Cherokee will be then one of the best mining towns in the State.

Calaveras.

THE MCFALL.—*Citizen*: The Ford Bros. are making quite a showing on their mine. They are down about 50 feet and the quartz looks very good. Quite a large percentage of sulphurets are to be found all through the rock, and we are informed that they carry considerable gold. The rock is getting somewhat softer, and more water is being encountered as they get deeper. Indications point to a good mine.

El Dorado.

VISITING MINES.—*Republican*, March 29: Col. Benyard and Major Heuer, of the California Debris Commissioners, accompanied by J. F. Kidder of Grass Valley, were in this county during the week, and visited the Snow mine at Newtown and a number of other hydraulic mines. The dam constructed by Snow Bros. to restrain debris was approved and a license issued for them to continue mining. In reference to the smaller mines in operation, the commissioners approve the selection of the sites for the restraining dams, but request that the obstructions to the flow of debris be raised higher, which is being done in compliance with the directions of the Commissioners.

Mariposa.

WITH A STRAM PLANT.—*Gazette*: The Ludwig mill will be in working order, as a steam plant, in a few days. Rock is being hauled from the Alarid mine, on the old ditch, to be tested as soon as the mill starts again.

Mono.

WATER SOURCE.—*Bodie Miner*: Paul Carroll and Pete Carroll are engaged in sluicing near the Dudley, and should water hold out they expect to make a few dollars. The scarcity of water this year practically knocks out what placer mining is usually carried on in this vicinity during the spring and summer.

Nevada.

THE WHITE DIAMOND.—*Transcript*: The work of putting up machinery at the White Diamond mine, about half a mile above North Bloomfield, was begun Wednesday. A five-foot ledge has been cut, and the quartz taken from it looks well. The shaft is down 75 feet. Bloomfield parties own the mine.

The Holiday quartz mine at Bloody Run, between Bloomfield and Moore's Flat, is being worked by Thomas Woon, Alex Dobbie, Jr., and W. Smith. The prospects are highly encouraging.

STROCK IR RICH.—*Transcript*: P. Norton, who has been working a quartz ledge this side of Lake City for a number of years, has struck it rich at last. The ledge is large and the quartz shows much free gold.

SALE OF A GRAVEL MINE.—*Herald*: Negotiations are about closed for the transfer of the

McKillican gravel property at Moore's Flat to the New York corporation who are to take a bond on it. It is a big deal. The New Yorkers are very wealthy men, and they propose to spend a large sum of money in developing this mine.

The mine is a big proposition. There is an immense deposit of gravel there known to carry gold in paying quantities. It would probably never be worked in any other way than by the drift process. Mining men believe that if the New Yorkers carry out their present plans they will have a mine which will rival the Derbec.

All this is good news for Moore's Flat and vicinity, and for Nevada City, for the matter of that. A number of men will be given work, and many thousands of dollars will be paid out for labor and supplies.

REPORTED SALE.—*Transcript*: It was reported in town Thursday, upon what appears to be good authority, that a sale of the Murchie mine property, of about 400 acres of patented ground, is about to be consummated. It is said that a company composed entirely of Scotchmen are to be the new owners.

STROCK OIL.—A dispatch from Carson, Nev., says: There will be another added to the resources of Mono county if the reported discovery of petroleum on the big island in Mono lake proves to be well founded. One hundred and sixty acres have been located by the following named persons: H. Boone, Judge Christian, Nat Boyd, Charles Radcliffe, James Patterson, Felix Deguirs, Pete Leonette and some other French-Canadians. They have formed a company and will develop the find to ascertain its extent. It is understood Boone will send for a boring machine at once.

The principal locators are Leonette and Deguine. They struck oil eight months ago, but did not bring in the petroleum until lately. They only received their naturalization papers this year. Some of the stuff brought in in a bottle resembles varnish, and some is in a crude state, of a dark greenish color. Both samples have been tested and found to be genuine petroleum. It has the coal oil smell and it also burns rapidly.

The strike has caused great excitement in and around Bodie, and it is stated that an effort will be made to interest Eastern capital, with a view to putting up refining works on a large scale if the flow holds out. As yet only meager particulars are obtainable. The amount of flow cannot now be stated, but it is reported to be sufficient to warrant development.

It is said the men were boring to strike water, and were surprised when they struck a flow of petroleum. There is no doubt about the genuineness of the discovery, however, and it is expected that the vicinity will be the scene of great activity in a few months.

THE OLD SEBASTOPOL.—*Union*: E. H. Baxter, principal owner of the Sebastopol, will shortly open up that mine and develop it. Negotiations are almost completed. An entire new hoisting and pumping plant will be placed on the mine and sinking commenced as soon as the water is forked. The Sebastopol is in a good locality. The mines now being developed on Osborne Hill are making good showings, and the old Sebastopol, years ago, under a crude system of mining, paid well.

A GOOD CLEANUP.—*Union*: The Wisconsin mine had a cleanup on Saturday of 167 loads of rock. The average outcome was \$60.57 per load, exclusive of sulphurets, which have a milling value of \$100 per ton. The company has on its dump, ready for milling, 60 loads more of the same rock, which will be crushed in the near future. The Wisconsin mine will prove a dividend-payer.

A NEW DEAL.—*Telegraph*: An arrangement was entered into between the Centennial Mining Company and Mr. H. Silvester, by means of which the company has been granted an extension of time for one year. This will enable the company to go ahead and thoroughly develop the mine, as all the preliminary work is done and the mine is free from water. The bottom drifts on the 650 level are being pushed ahead and there is a fine ledge visible in these drifts, as well as in the shaft. Mr. Larkin, president of the company, returned to Sacramento lately. All work at the mine will be vigorously prosecuted, and the best-posted miners in this district predict a rich strike in the near future.

Placer.

THE HIDDEN TREASURE.—*Republican*, March 30: Harold T. Power, of the Hidden Treasure mine at Sunny South, was in Auburn this week. Over 190 men are now employed in the mine, and the yield is very satisfactory. Mr. Power states that the past winter has been the most severe and most disagreeable he has ever experienced on the divide. Up to Tuesday last the road had not yet been opened to the mine for teams, and supplies were yet being taken in on sleds. It was expected, however, to have the road open by Wednesday.

San Bernardino.

AMONG THE CHLORIDERS.—*Vanderbilt Shaft*, March 30: Last Monday we took a stroll around to see the different chloriders in camp, and it was one of the pleasantest trips we have made lately. There is nothing more agreeable than to visit a man at his work when he is doing well and is full of hope; therefore, as there is not a discouraged chlorider in camp, it does a person good to talk to them.

Fox, Phillips and Freethy have a lease on the Bronze and are doing remarkably well. They work hard, have a good vein and their ore is rich, very rich. From one horning made recently the gold obtained weighed 25 cents.

Anderson and Makepeace have a lease on the Gore and are digging out good rock. Charlie McDonald also has a lease on this claim and is

doing well, his ore being very rich. Eddy and More have just taken a lease on this claim.

Marrs and Congdon, who have been working a lease on the Chippie for two months or more, and who have been doing well, are still taking out some very rich rock, a recent assay showing a value of about \$250. They have a lot of ore on the dump. Mr. Ewing commenced work Tuesday on a lease on this claim.

A short time ago I. Howell made a deal with A. G. Campbell by which Mr. Howell became owner of the Alta mining claim. Mr. Howell is now working this claim and has considerable fine ore on the dump. He will put some through the arrastra soon. Jim Orr is helping him in the mine.

John Alphin is looking for a good place to begin chloriding.

W. V. Trask and S. C. Spence are getting some good hornings out of the eight-inch vein on their lease on the Oversight. They are bound to make some money.

Kilpatrick and Grundy have a lease on the Monte and have sunk upon it a 35-foot shaft. They will now commence to drift. They have a good vein of ore and will do well.

E. D. Mulcahy has a 30-foot tunnel on the Iron claim. He is taking out ore now, having run his tunnel along the vein without disturbing the ore. He has a good showing.

Craig and Gordon have as good a body of ore as any chlorider in camp. They have a lease on the Webster, and their vein averages about eight inches in width, some of which runs very high, a recent assay showing a value of \$450. Juan Tapio took a lease on the Nugget about two months ago, and he is doing as well as any chlorider in camp.

Shasta.

DRIFT MINING.—*Redding Free Press*: The mining enterprise inaugurated some time ago by E. Parsons, deceased, on Oregon gulch, promises to result in something substantial to those interested. Mr. Parsons had made a study of geology, and had come to a positive conclusion regarding the existence of a prehistoric river which ran through this county before the advent of white men. The formation in Oregon gulch was of such a favorable character, in accordance with his ideas, that he organized a company and proceeded to sink a shaft. After going down vertically 40 feet he ran an incline shaft at an angle of about 30 degrees which is now 100 feet deep and has penetrated a sandstone formation and developed gravel containing gold, but hardly in paying quantities as yet.

The manager of the company, which is known as the Sacramento Pliocene Mining Company, is Dr. McLean of Sacramento. This week he shipped up a 20-horse power hoisting engine, with other necessary machinery, by the aid of which he hopes to facilitate the work, and he expects to strike an entirely different bed of gravel than that encountered and which is supposed to hold gold in such quantities as to pay the stockholders well. So far, Parson's theory has proven correct and good results are therefore expected.

Siskiyou.

RICH PAY.—*Yreka Journal*: The Greenhorn Blue Gravel Mining Company continue to take out rich pay every day, and the men employed are now running two tunnels from the hoisting and pumping shaft—one toward the hill, where such good pay was realized in the tunnel from the old shaft, and another toward Lee's house, where the good pay gravel was first discovered. This is likely to be an excellent season in working this claim, by reason of a greater amount of water than during most seasons to keep the sluices well supplied for washing the gold.

The quartz miners near the junction of Shasta and Klamath rivers are making preparations to commence work again as soon as the ground dries out, as it is too wet now for successful work. The water drips down in great quantity, and timber is scarce in the vicinity, with almost impassable roads for hauling by teams at present. This camp is called Fool's Paradise, but there is no foolishness about the existence of rich paying ledges, which will yield handsomely when well developed.

The Klamath river miners in Honolulu district have already commenced making preparations for putting in new wing dams, by getting out timbers and securing lumber for the purpose. They will be prepared for active operations as soon as the river reaches its normal level, and expect to realize good pay all summer until late in the fall. The heavy freshets during the past winter have cleared the stream of a great amount of tailings which covered good pay ground as an incumbrance, hence we may anticipate lively times all along the rich paying Klamath river from Hornbrook in the Cottonwood district down to the Virginia Bar, Honolulu, Oak Bar, Hamburg, Seiad Valley and Happy Camp districts, in this county. Good river diggings will also be worked with success on all the tributaries of the Klamath, especially the Salmon and Trinity rivers in Siskiyou, Humboldt and Trinity counties.

The miners in the high gulch diggings are getting ready for ground sluicing now that the snow is dissolving rapidly, but the snow is very deep yet for good progress, especially on the shady sides where the sun does not get much chance to melt it.

RICH LEAD.—*Journal*, April 4: Wiley Parker has located a rich ledge on Portuguese gulch, a tributary of Humburg gulch, west of Yreka, which carries free gold in nuggets and may develop into a large and valuable ledge. The croppings, however, are very thin, only 2½ inches wide, but this stringer may lead down to a wide ledge when tested in sinking a shaft. Besides the nuggets in the shaft, there is probably considerable fine gold.

The hydraulic miners in the Salmon river section are all busy with their giants in piping down the banks and are having excellent success in taking out gold dust. There is a greater

abundance of snow on the high mountain peaks than for several years which will keep up the water supply later than usual. The quartz mills are also grinding up rich quartz, with likelihood of water power to keep them going until fall.

Work has been commenced in the Campbell & Co. hydraulic mine in Quartz valley, the pay gravel being now raised to the surface by hydraulic elevators, in preference to drifting.

The Greenhorn blue gravel mine, a short distance south of Yreka, continues to pay about a dollar to each bucket hoisted, and as the claim is more thoroughly opened, double the number of buckets may be hoisted, to double the yield of gold.

Frank Hall, the well-known mining operator, is considering the matter of starting work again in the old Ballarat claim, on Yreka flats, north of Yreka, where good pay is believed to exist, the company working it never having gone down below the rimrock of the channel.

Eastlick & Lewia Brothers have a fine ledge of quartz at Oro Fino, which averages about three feet thick, and is eight feet thick in places. The quartz so far crushed has paid about \$10 a ton, with steady improvement.

The hydraulic claims at Oro Fino are in full blast, with an abundance of water to keep the quartz mills in operation until late in the summer.

William Shell, at New Pinery, in Scott valley, is taking out good pay, doing effective mining work by blasting with giant powder, and ground sluicing.

Tuolumne.

MOUNTAIN MINES.—*TO THE EDITOR*: The Louisiana mine is situated near Cherokee. It is a full claim of 1500 feet and is in granite formation. It has been opened by two shafts. The main shaft is down between 300 and 400 feet, and several levels run north and south on the vein. The ore is free-milling, with some sulphurets. Considerable gold has been taken out of this mine, which is now idle; and if reopened, would no doubt make a paying property. Water power can be had for the mill, hoists, etc.

The Laura mine, situated east of the Louisiana, is now working. The shaft has been sunk 200 feet, which makes it 400 feet, and they are now running drifts from the bottom. The hoisting works are a small upright boiler and engine; but when the mine is opened, and proves a success, water power will be used. A fall of about 500 feet can be had from the Soulsbyville ditch with about 4000 feet of pipe.

Col. J. L. Coles and brother, D. H., late of Montana, have bonded the Buckeye, Wooster and Mayflower mines, south of the Eureka Consolidated. They expect to commence operations in a short time.

Owing to the severity of the past winter, work was almost suspended on the Black Oak mine at Soulsbyville. The water has been pumped out of the mine again and a full force of men put to work. I am informed the vein in the bottom of the shaft is six or eight feet in width and is high-grade ore. There is a large percentage of sulphurets which go well up into the hundreds. The shaft is now a little over 600 feet in depth and is a fine property. There is a good hoist and mill on the property run by water obtained from the Tuolumne Water Company.

The Live Oak is south of and an extension of the Black Oak. It is owned by the same company. A ditch is now being made to the mine and the hoist will be run by water power. The Live Oak is a good property, and as soon as opened up again will pay a good dividend.

It is rumored that the Pennsylvania mine, south extension of the famous Soulsby, will be opened this summer. There is good ore in the Pennsylvania; and, as the Soulsby has been one of the best mines in the county, we have good reasons to think the Pennsylvania will be a valuable property.

The Carlotta mine at Cherokee is a good mine, but is now idle. Considerable gold has been taken out and the ore is of a high grade. Ore of a high grade has also been taken out of the Porto Fino, which joins the Carlotta. Good water power can be had, and mines can be opened with small capital.

The Seminole, which was bonded a few months ago by a San Francisco company, is now turning out good ore, and they have men grading out for a ten-stamp mill.

The Eureka Consolidated is working steadily and paying its men promptly. Twenty stamps are dropping day and night, which is good evidence that it is a prosperous paying property.

A ledge was lately discovered at Arrastraville by Cullers & Co. which shows gold. They have a few tons of ore out and it looks well.

Mr. J. E. Summers says he has discovered a new vein near the Mayflower which is two feet and shows gold freely.

April 3, 1894.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—Following is a summary of the official reports for the past week from the Comstock mines:

Consolidated California & Virginia—1650 level.—The drift running north from the end of the crosscut run east from the drift run north from east crosscut No. 1 from the north drift from the winze—down 52 feet—has been extended during the week 19 feet; total length 69 feet, continuing in porphyry, clay and quartz of nominal value. Have extracted from our workings in the vicinity of the winze—down 20 feet—16 tons of ore assaying \$47 per ton. We are doing some necessary repair work in the main south drift and openings therefrom on the 1600 level. 1000 level.—The Rule drift—From the upraise from this drift, started at a point 353 feet south of the shaft—60 feet up—an east crosscut has been started and advanced 20 feet; in porphyry and clay formation. At a point 50 feet up in this

upraise a north drift has been started and advanced 25 feet; in a porphyry formation. East crosscut No. 2, started from the drift at a point 527 feet from the shaft station, has been extended 30 feet; total length, 115 feet; face in porphyry, clay and quartz of low assay value. Opposite this east crosscut a west crosscut has been advanced 15 feet in vein material, showing quartz of a low assay value.

Ophir—1465 level.—The crosscut running west from the drift run north from the crosscut run west from the main north drift on the sill floor of this level at a point 124 feet south from the winze station has been extended during the week 12 feet; total length 60 feet; continuing in porphyry showing clay separations. Central tunnel.—The north drift from the main west drift has been reopened and repaired 84 feet; total length 142 feet. Have continued, jointly with the Mexican Company, the work of making repairs to the main shaft.

Mexican—1465 level.—The upraise started near the mouth of the crosscut run west from the drift run south from the top of the upraise which was carried up 45 feet above the sill floor of this level at a point 40 feet from the main north drift and 100 feet north from the south line of the mine has been carried up during the week 11 feet; total height 51 feet; formation hard porphyry.

Union Mine—900 level.—The Union Con. and Sierra Nevada joint east crosscut near the north line of the Union mine started from joint north drift, which was run from the joint west drift at a point 1520 feet west of shaft, has been extended during the week 21 feet; total length, 191 feet; face in clay and porphyry.

Andes—420 level.—West crosscut No. 3 has been extended 17 feet; total length 124 feet; formation hard porphyry.

Best & Belcher—900 level.—The east crosscut which is being run on the north boundary has been advanced 18 feet during the week; total length, 449 feet; face in soft porphyry and seams of clay.

Gould & Curry—200 level.—West crosscut No. 5 started in northwest drift 432 feet from the main west drift has been extended 18 feet; total length 975 feet; face in hard porphyry.

Hale & Norcross—900 level.—Advanced the south drift 10 feet; total length, 157 feet; face in porphyry. 1100 level.—Advanced the south drift 13 feet; total length 155 feet; face in porphyry.

Sierra Nevada.—The south lateral drift from the intermediate tunnel has been advanced 28 feet; total length, 543 feet; face in clay and porphyry. The joint east crosscut near north line, from the north drift 1520 feet west of the shaft, 900 level, has been advanced 24 feet; total length, 191 feet; face in clay and porphyry.

Chollar.—The north drift, 100 level, is now out 80 feet; the face is in low-grade quartz. The west drift, 300 feet south of north line, 100 level, is out 50 feet; face is in porphyry.

Potosi.—The south drift on the 450 level has been advanced 20 feet; total length, 272 feet; face in porphyry and streaks of quartz. The raise from the northwest drift, 450 level, is up 58 feet; top in low-grade quartz and porphyry.

Ballion.—The west drift from the station, 820 level, Ward shaft, is out 675 feet from the shaft; face in porphyry.

BLANKET SLICING UNPROFITABLE.—*Enterprise.* The owners of the blanket slicers in Six-mile Canyon find it very difficult to make expenses on account of the tailings escaping into the creek from the Nevada mill containing only a small percentage of sulphurets, and this, coupled with the low price of silver, has reduced the margin above expenses to a minimum.

From 1879 to 1880 blanket slicing in the canyon was very profitable. During those years there were twelve stamp mills in operation, the tailings from which flowed into Six-mile Canyon creek, which at that time was almost a solid floor of slicings from the Nevada mill to the mouth of the canyon.

The large percentage of metal mingling with the creek water colored it blue as steel, and a bucket of the material dipped from the stream at any point showed an average assay value of from \$3 to \$4 per ton in the sediment at the bottom. When the flow was concentrated on the blanket-covered tables the sulphurets showed an average value of about \$30 per ton, and the owner of two strings of blanket slicers west of Flowsy, and a plant of two amalgamating pans, cleared from \$500 to \$800 monthly for several years.

Several owners of blanket slicers have concluded to abandon sweeping this summer, and will put strings of placer flumes in the creek to prospect the ground down to the bedrock, where coarse gold is frequently found, but so far, not in quantities sufficient to pay. That found, however, is rough and jagged on the edges, indicating that it has not traveled far, and the chances are favorable for finding gold-bearing quartz seams in paying quantities in the bedrock.

Kennedy District.

THE MILL A SUCCESS.—*Silver State.* The mill at Kennedy, under the able supervision of John Ross, Jr., started up last week and is working like a daisy. The yellow metal will be turned out lively now and the only drawback will be the capacity of the mill, as the camp is full of good ore and the mill is not large. Kennedy will no doubt be a booming place this summer, and great credit is due Mr. Jenkins for his pluck and confidence.

ARIZONA.

A DOS CABEZAS PRODUCT.—The property of the Cochise County Marble and Onyx Co., which is located in Dos Cabezas district, about eight miles from the town of that name, has come into prominence. The Phoenix Republican says Secretary Coon has just received some of the polished stone which had been

sent to Tennessee. It attracts much attention. The samples are accompanied by a letter from Mr. John L. Hart, secretary of the East Tennessee Marble Co., a gentleman so regarded as an expert that he was summoned before the Ways and Means Committee during its deliberation upon the marble schedule of the Wilson bill.

Mr. Hart writes that the marble is of the highest grade and that the samples sent represent only about one-third of the variety forwarded from the quarry for polishing.

The stock of the company is owned by Tennessee marble quarry men.

FINR SHOWING.—*Mojave Miner.* The showing in the Buckeye mine is said to be far ahead of anything ever seen in the Rural in its balmy days. The ore is very high grade and the bunches of solid native silver are immense.

The Gold Mining Company of Music mountain has, at a small estimate, \$25,000 worth of ore blocked out in the mine and on the dump. The ore will average fully forty dollars in free gold.

John Smithline, who has been at work on the Lucky Boy mine, on the west side of Sherman's Peak, assorted about five tons of ore and brought it into the sampler this week. The ore will average about 350 ounces in silver per ton. He has a splendid showing of silver ore in the mine and will do much more development on the property when he returns home.

The main shaft on the Tennessee mine at Chloride is now down seventy feet and still going down. Owing to the large volume of water encountered, a steam pump and hoist will have to be put in. The shaft has been securely timbered and the loose ground that was found so troublesome a few weeks ago has been caught up securely. The shaft is all in ore of a good grade.

TROUBLE AT THE CONGRESS.—*Tombstone Prospector.* April 2: It is reported that serious trouble has been caused at the Congress mine by the appearance of 18 Italians, who have been put to work in the mine. A large number of American miners appeared there for work and demanded that the Italians be discharged, threatening the life of the foreman unless their request was complied with. Matters were in this condition when our informant left.

IDAHO.

BUNKER HILL AND SULLIVAN.—*Wardner News.* Work in the Bunker Hill and Sullivan mines proceeds with accustomed regularity, and the new electric hoist, which was put in operation on Monday, is working most satisfactorily. New wire rope has arrived this week from the Trenton Iron Works, New Jersey, and will be placed on the line between the Reed ore bin and the first snow shed.

MONTANA.

BIO MINING SALE.—*Helena Independent.* The biggest mining deal made in this State in a long while is the sale of the Golden Sunlight group of mines, in Jefferson county, near Whitehall, to a New York syndicate for \$500,000. The first payment on the purchase has been made. A few days after the sale of the Golden Sunlight group came the news of the sale of the Poorman mine in the Coeur d'Alene country to an English syndicate for half a million. These two sales for such large sums, coming so close together, indicate that capital is ready to go into mining where there is something in sight to justify an investment. They also show that capitalists regard legitimate mining enterprises as good investments which will return a good interest on the money put into them. The good effects of the sale of the Golden Sunlight group are already felt in the neighborhood in which the mines are located, reports from there being to the effect that many properties that have lain idle for a long time are going to be developed this season, and that prospectors are only waiting for the snow to go off in order to start out into the hills.

OREGON.

RICH POCKET.—*Jacksonville Times.* Messrs. Knott, Swinden and Birdsey have struck a rich pocket in their mine in Kane creek district.

E. K. Anderson and Crit Tolman are pushing work on their quartz mill in Wagner creek district, and are nearly ready to commence crushing ore.

Dr. Taylor & Co., who have the Rummel & Legate quartz mines at the head of Rider gulch, near Henley, Cal., bonded, have put a force of men to work on them.

B. F. Dunphy of Portland is prospecting the Miller Hydraulic mine on Farmer's flat, with a view to purchasing the same. A price has been agreed on for the property under certain conditions; but no sale has been consummated or bond given as yet. This is one of the best placer mines in southern Oregon, and should bring a good price.

Carter Bros. are extensively engaged in mining on the old Kilgore place in Ashland precinct, with good prospects of a big cleanup. They have 1300 feet of hydraulic pipe, and having the use of several miles of new ditch from Wagner creek, will wash a good deal of ground during the season. Messrs. Carter are full of energy and have been interested in a number of mining enterprises.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

Market Reports.

The Markets.

SAN FRANCISCO, April 5, 1894.

The silver market has shown decided improvement during the week. The veto of the Seigniorage bill relieved the tension, and had a directly contrary effect to what might have been expected during the week—if it had any effect at all. The improvement is in part due no doubt to a growing confidence that European nations must make a positive movement toward the rehabilitation of silver. The indications are now more favorable than they have been for some time.

After steady improvement for a week in silver, prices receded to-day, the New York price being 61 1/2¢; London, 27 1/2¢.

There are no important changes in copper and lead.

Coinage in March.

The coinage of the San Francisco Mint in March was as follows:

Descriptions.	Amount.
Double Eagles.....	\$1,250,000
Eagles.....	250,000
Half Dollars.....	269,948
Quarter Dollars.....	90,000

Total.....	\$1,859,948
January.....	2,500,000
February.....	2,380,000

Three months.....	\$5,799,948
Same time in 1893.....	7,890,000

Decrease in 1894..... \$590,052

The total for the same time in 1892 was \$7,036,189, against \$11,173,536 in 1891.

The total coinage during the first nine months of 1893-94 was \$18,051,288, against \$18,603,121 for the same time in 1892-93.

New York Prices.

NEW YORK, April 5.—Following are the closing prices for the week:

	Silver in	Copper.	Lead.	Tin.
Thursday.....	27 1/2	59 3/4	9 50	3 40
Friday.....	27 1/2	59 3/4	9 50	3 40

Mining Share Market.

SAN FRANCISCO, April 5, 1894.

The Comstock market has during the week been more healthy than the week before. The feature of the week has been that Opbir is at the head of the list, passing Con. Cal. & Virginia. During this forenoon it sold up to \$3, the highest price it has touched for two months. Con. Cal. & Virginia had to play second fiddle. The cause of Opbir's advance is the resumption of exploratory work in the surface ground in the western part of the mine, through the old Central tunnel and its branches. In a few days a connection will be made between the north drift from the tunnel and the old Mexican shaft, and after that some crosscutting in interesting places will begin. Gold rock giving fair assays has already been found in the drift.

In the middle group of stocks this morning a steady advance in Potosi right in the face of the 25-cent assessment, which will be delinquent to-morrow, greatly encouraged the others, and there were large purchases of Chollar, Bullion, Savage and Hale & Norcross at higher prices.

Below is a statement of the sums disbursed to employees of Comstock mining companies for services during month of March: Hale & Norcross, \$2194.25; Con. California & Virginia, \$8783; Opbir, \$2695.25; Mexican, \$2299.25; Keniluck, \$894; Bst & Belcher, \$2119.50; Gould & Curry, \$1338; G. & C. and B. & B. shaft, \$124; Alta, \$1966.50; Occidental, \$737; Justice, \$1199; Crown Point, \$2382; Yellow Jacket, \$3014; Belcher, \$2514; Seg. Belcher, \$671; Scorpion, \$3004; Savage, \$3700; Chollar, \$3757; Potosi, \$3465; Union shaft, \$2113.50; Alpha and Exchequer, \$603; Ward shaft and Bullion, \$7448; Sierra Nevada, \$4445; Nevada mill (estimated), \$2500; water company (estimated), \$3000; quartz mills (estimated), \$7000; total, \$62,602.75. The pay rolls aggregate \$606.75 more in March than in February.

It is reported on the Comstock that the Gold Hill Miners' Union will meet in a few days and take another vote on the wages question. A large majority of the members are understood to favor a reduction in wages from \$4 to \$3 per day.

Coast Industrial Notes.

—The wages of the Benicia tanners have been cut 10 to 20 per cent.

—Owing to the rise in the Columbia, half of the 600 men employed on the canal and locks at Cascades were discharged Saturday.

—The daily capacity of the eighteen shingle mills in British Columbia is 1,380,000 shingles, and a kiln capacity of 985,000.

—A factory is to be started at Grant, Or., to make a new kind of plow invented by a man living across the river to Klickitat county.

—The railroad company has in course of construction at Sacramento a portable plant for treating ties with a preservative compound.

—The Banning Herald professes to have information that a natural gas well with a strong flow has been struck by persons boring a well in Los Angeles.

—The Arizona Land Court has decided that land grants made by the Mexican States are void. This affects the titles of grants aggregating nearly 75,000 acres.

—At Stockton the Union Flouring Mill is to be taken into the mill combine. Stockton people think this will result in the consolidation of the competing steamer lines, or the raising of passenger and freight rates, or both.

—The United States Court of Private Land Claims, which has been in session at Tucson, A. T., for some days, has adjourned after handing down a decision in the Sonita, San Rafael del Valle, Babacomari and Nogales de Elias grant cases, favoring the settlers.

—The snowfall in the Cascade mountains this winter has been enormous along the Great Northern road. Up to a week ago it had been 63 feet 7 inches on the summit, and after settling it lay 26 feet 3 deep on the level, being above the tops of the telegraph poles.

—The Census Bureau furnishes the following statistics for the Pacific coast concerning the total value of real and personal property. The totals are as follows: California, \$2,533,733,627; Oregon, \$590,396,194; Washington, \$760,698,726; Nevada, \$180,323,668; Utah, \$349,411,234; Arizona, \$188,880,976; New Mexico, \$231,459,857. The same figures for California in 1880 were \$1,343,000,000.

—Vallejo's electric light works were sold at auction Tuesday to satisfy a claim of \$10,000. There were scarcely any outside bidders present, and Sheriff Henderson was forced to knock the works down to ex-Senator James McCudden for \$2800. Since the sale there has arisen a rumor that the Court will not confirm the sale, as there are reports of collusion. Since the inauguration of the Vallejo electric light works the company has been involved in many legal tangles. For the past two weeks the works have been shut down, leaving Vallejo in total darkness and many residences without light.

—The Market-street officials are figuring on the construction and equipment of an immense power-house at the corner of Channel and Bryant streets, which shall be of sufficient capacity to run all the various lines of road which it is contemplated to operate by electricity in the city. At first the boiler capacity, it is estimated, will approximate 1500 to 1800-horse power, but it is proposed to provide for a possible increase of these figures 6000 or 7000 in a few years. The Howard-street line, the South San Francisco and the Third, Fourth and Fifth-street lines will, it is contemplated, be operated by electricity before many months, and the Mission-street line, it is anticipated, will be in working order some time in June.

Electrical Transmission of Power.

We desire to direct the attention of Mine Owners, and others, to the subject of Long Distance Transmission of Power, by means of electricity.

The successful operation of these plants means much to the mining interests of this State where fuel is high, for the utilization of the water power of the State will make low-grade ore pay handsomely. The saving to be effected by electric power transmission has been demonstrated at Bodie, Cal., where the Standard Mine Co. installed a plant for transmitting 150 H. P. a distance of 12 miles. In his report to the stockholders, dated February 20, 1893, the president says:

"In 1891 we expended \$21,607.75 for mill fuel, or an average of \$1780 per month. In 1892 the expenditure for the same was \$22,758.30, or an average of \$1896.52 per month."

This entire expense is now being saved, and with no more attention than with the steam plant. The saving effected will pay the entire cost of the installation in less than two years.

The Pacific Electrical Storage Co., 118-120 Pine St., San Francisco, has made a specialty of electric transmission, and has thoroughly competent and reliable engineers to design and install any kind of plant, the working of which they will guarantee.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co.,* Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MARCH 27, 1894.
517,206.—TRACT HARROW—H. Baker, Santa Rosa, Cal.
517,183.—WINDOW SCREEN—C. H. Bartlett, Jr., Pomona, Cal.
517,021.—HAME AND COLLAR—D. K. Bill, Hillsborough, Oregon.
517,041.—FRUIT PICKER—W. H. Haw, Fields Landing, Cal.
517,219.—TRACT—E. Hickman, Red Bluff, Cal.
517,118.—BUBBLER BLOWER—P. D. Horton, Oakland, Cal.
517,223.—CANE—John Lee, San Mateo, Cal.
517,380.—CAR COUPLING—J. D. Locke, Cosumne, Cal.
517,412.—DELIVERING OODS—A. F. Martel, S. F.
5,791.—ADOINO MACHINE—W. K. Nichols, S. F.
517,192.—HOB COUPLING—J. M. Prior, Carson, Nev.
517,362.—STUMP EXTRACTOR—G. B. Pulley, Clovis, Or.
517,194.—TRUSS—C. B. Roethel, Jacksonville, Or.
517,243.—TELEPHONE SYSTEM—Salis & Hampton, S. F.
517,305.—DISCHARGE FOR CANS—A. H. & T. A. Schriener, Oakland, Cal.
517,365.—HARROW—S. Shoemaker, Shasta, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

TRACT HARROW.—Henry Baker, Santa Rosa, Cal., assignor of one-half to George E. Guerne of same place. No. 517,206. Dated March 27, 1894. This harrow, as its name implies, is especially adapted for use on race tracks, to which it is particularly applicable by reason of the mounting of its teeth and the adjustability of its frame, making it possible to be readily set and conveniently and effectively used in preparing and dressing the surface of the course. The harrow is composed of a tooth-carrying frame, supported at its rear upon a rocking axle which has end cranks upon which the wheels are mounted. A swinging clevis at the front of the frame carries the front wheel, and this clevis is connected by a rod with the lever which rocks the crank axle, thereby vertically adjusting both ends of the frame simultaneously. The teeth are secured in sockets in the outer sides of the bars by plate bolts to said bars. By loosening a plate near a tooth the latter may be raised or lowered or removed for the substitution of another. Thus the required uniformity of adjustment necessary for the particular use of track harrowing can be easily and accurately effected.

TRUSS.—Carl C. Rostel, Jacksonville, Or. No. 517,194. Dated March 27, 1894. The object of this invention is to provide an elastic-truss belt, which is adjustable in length to suit the size of the person, for the purpose of placing the pad or pads at the proper point without altering their position upon the belt; to provide a pad or pads with an elastic pressure device, the tension of which is adjustable to any part of the pad, and to any degree of strength; and to provide certain relieving pads to prevent soreness at points where the belt passes around the pad. The whole invention is designed as an improvement in that class of apparatus which is employed for the treatment of beria.

SELF-REGULATING DISCHARGE FOR CLOSED VESSELS.—A. H. & T. A. Schleuter, Oakland, Cal. No. 517,305. This invention relates to a discharging apparatus for closed vessels of any kind contain-

ing liquids. The object is to provide a means for allowing liquid to flow from an air-tight vessel whenever the discharge passage is open, and for arresting the flow from said passage whenever the receptacle has been filled to the proper height, and to prevent the overflow of the receptacle. With this apparatus it may be effected with any hermetically closed vessel, cask or other containing device.

Assessment Notices.

SUPERIOR MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Placerville, El Dorado County, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 13th day of March, 1894, an assessment (No. 1) of Twenty Cents per share was levied upon the capital stock of the corporation, payable immediately in United States Gold coin, to the Secretary at the office of the company, Room 17, 318 Pine street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 14th day of May, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors.

R. W. HEATH, Secretary.

Office, 815 Pine St., Room 17, San Francisco, California.

MINING & MILLING MACHINERY,

ADAPTED TO EVERY DESCRIPTION OF MINING AND MILLING.

OFFICE AND BRANCH WORKS,

213 FIRST ST., SAN FRANCISCO, CAL.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED }
{ Sept. 19, 1893. }

CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.

{ FRANK BARRERE, }
{ Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE COMPANY'S WORKS, 180 MAIN STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

—SAVED—

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Pumping Belt, SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, 100, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing OLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 32 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

A 1000-Horse Power Two-Phase Alternator.

The illustration on this page is most interesting as furnishing in some degree an idea of the tremendous development of electric power and electric power appliances during the past few years. It is the two-phase alternating generator, 750 kilowatt, shown at the Columbian Exposition by the Westinghouse Electric & Manufacturing Company of Pittsburg. It has 1000-horse power.

All alternating current generators (usually known as alternators) must have the magnetism of their fields excited by a direct current. As distinguished by the source from which this exciting current is obtained there are three classes:

1st. Separately excited alternators, which derive the excitation of their fields entirely from a separate dynamo, called an "exciter."

2d. Composite wound alternators, which receive a part of their exciting current from a separate exciter and a part from their own armatures.

3d. Self-excited alternators, which have their entire field current supplied from their own armatures.

Alternators usually deliver current at higher potentials than are allowable in direct current machines adapted to incandescent lighting. Economical distribution of electrical energy over long distances requires the use of high pressure, but this is practicable only in alternating-current systems, which, while employing very high potentials in the distributing circuits, are able to supply low potentials to the lamps by means of the transformer. The alternator itself possesses a great advantage over the direct current dynamo in the fact that its current is delivered to the circuit through ring collectors and not through commutators, which are exceedingly troublesome where the attempt is made to employ high potentials.

Alternators derive their name from the fact that the current which they deliver is reversed in the direction of its flow many thousand times a minute. It is evident, therefore, they can have no continuously positive (+) or negative (-) brushes.

There are several types of two-phase alternating current generators, among which two are especially prominent. Machines of the first type are really double machines, having two fields and two armatures—the latter mounted on the same shaft. Each armature delivers alternating current to a two-wire circuit, and these circuits taken together constitute the four-wire circuit of the generator, or

they may be so connected as to constitute a three-wire circuit.

Machines of the second type have single armatures with two windings, or with a single winding so connected to the ring collectors as to deliver two currents differing in their time relation or phase. In place of the commutators ring collectors are used, but in other respects the construction is not materially modified.

The illustration presented upon this page is of a 1000-H. P. generator of the first-mentioned class. It is practically a double machine, consisting of two fields mounted upon the same headplate, and two armatures carried upon

Miners' Wages Will Not Be Lowered.

There are strikes and strikes. Some are successful, others not; some are justifiable, others not. Miners' strikes in the Pennsylvania mines are of frequent occurrence; and they are, or have been, by no means rare in the West. But a strike in California is an uncommon occurrence. It is not difficult to explain the reason, which is that miners' wages are low and there is absolutely no pretext upon which they can be justly made lower. It should be added, also, that the absence of unionism among the miners is an influence that must be considered. It must

not be understood by this latter statement that there is want of fraternity, or of mutual dependence and helpfulness among miners, or of common inspiration to assist one another in time of need. California miners are loyal to themselves and to one another. There is no class in which there is more genuine charity and unselfishness and willingness to follow out the precepts of the golden rule.

THE celebrated Tyler-Last Chance mining case, on appeal from Idaho, has just been decided by the Federal Court of Appeals in this city, in favor of the Tyler. The litigation has been of years standing, and has involved the expenditure of vast sums of money. The claims adjoin, and the trouble was, like many others, as to disputed ground.

750 KILOWATT TWO-PHASE ALTERNATOR, MADE BY THE WESTINGHOUSE COMPANY.

the same shaft. As in the two-wire synchronous system, the fields are circular castings, having inwardly projecting poles of laminated steel, while the armatures have T-shaped teeth of similar material, beneath which the coils are wedged. A belt-driven generator of this type weighs about 75 tons.

A REPORT has gained circulation that the great Utica mine at Angels is about to be sold. The rumor is that the mine is to be sold to the Brownlow Syndicate, London, for \$29,000,000. The mine has stood in the name of Alvinza Hayward, the heirs of the Hohart estate and Charles E. Lane. It is said to be the desire of the Hohart heirs to dispose of the property, because they wish to partition the estate, otherwise the rumor would appear to have no color. The Utica mine is the best paying gold mine in the country. It is free milling and pays over \$42 to the ton. There are about 200 stamps working at the mill and the men employed number not less than 150 in each of the shifts. The mine yielded over \$1,000,000 last year, a very large part of which was profit.

The Last Chance extended its workings into Tyler territory. It is said the Tyler is owned by men who are not practical miners, and if they desire to work the ore body they have just won, will have to purchase the Last Chance to use its side hill for the works. Rather than do this it is believed they will sell to the new parties. As the Tyler mine stands now it is the cheapest big property ever developed in the northwest, as the work the Tyler people performed was nominal, while the Last Chance expended upwards of half a million dollars before the big ore body was struck. When the Tyler commenced its suit damages were asked in \$200,000 for the value of the ore removed from the disputed ground. In the verdict given in the United States Circuit Court at Moscow the damages were not considered, the court holding that the right to the property should be first established and the claim for damages could then be taken up and an accounting had. This still remains to be done.

THE total output of coal from the British Columbia mines for 1893 was a little more than 1,000,000 tons.

 THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 239.

Assessment Work for 1894.

The desire of many miners that the provisions of the law suspending assessment work for 1893 be extended to 1894 meets with a great deal of opposition in Congress. True, no test of sentiment has yet been made, but it is a fact that when the bill for 1893 was proposed it also included 1894. This proposition encountered much objection, and, to save the bill, Congressman Bell, of Colorado, went before the House Committee and consented to an amendment striking out 1894. In this shape the measure became a law; otherwise, it was certain to be defeated.

It cannot be said that the miners of the gold States take a great deal of interest in the measure; at least they do not by any means consider it vital to their welfare. In the silver States the matter is regarded quite differently. If it were possible to exempt the silver mines only, there would be no great objection to suspending the provisions of law in their favor alone; but it is not. If any mines for precious metals are favored, all must, in the nature of things, be included. Whatever is done, it is desirable that it be done very quickly. We think it probable that a bill for 1894, containing exactly the same provisions as last year's law, can be passed by this Congress; but it ought to be done at the present session before any assessment work is done and while all have a chance to secure its benefits.

THE silver question before Congress appears to have gotten into a curious situation. If we are to credit newspaper accounts, it is about as follows: In the last paragraph of his veto message the President intimated that he would sign a bill for the coinage of the seigniorage if coupled with a provision empowering the Secretary of the Treasury to issue bonds. This action on the part of the President seems to have split the silver men into two factions. Some of the free-silver Congressmen are willing to accept this as the solution of the problem, glad to get something to go to their constituents upon, but the greater part of them declare that they will never consent to the issue of bonds.

The Administration Democrats, on the contrary, are nearly all anti-silver men, and while willing to grant bonds will not vote for the coinage of the seigniorage. This is also the position of the anti-silver Republicans. In view of all this, the free-silver men find themselves divided and can really look for aid no quarter.

THE California Debris Commission has issued a permit to the Snow Bros. to operate by the hydraulic process a mine near Newton, El Dorado county. The approximate capacity of the restraining reservoir to be constructed is 161,000 cubic yards. Authority has been given for the construction of debris dams to James Hackett of the Oriental and Tahoe mines at Rough and Ready, Nevada county; also, to Pascoe & Gruben, in the Eureka hydraulic mine near Placerville, El Dorado county.

Title to Railroad Mineral Lands.

A case whose determination is of direct consequence to miners of many sections of the West was argued in the Supreme Court of the United States last Wednesday. Its title is *Braden versus the Northern Pacific Railroad Company*, and the question at issue is as to the interpretation of the Northern Pacific Railroad grant in that clause excluding mineral lands from its operation. The facts of the case are briefly that Braden attempted to secure patent to mineral land on an odd-numbered section within the railroad domain from the land office by conforming to the usual requirements. The railroad company resisted the issue of patent on the ground that title to all land in odd-numbered sections within their domain was expressly vested in them by the Government, except that known to be mineral at the time they filed their definite map of location. It will at once be seen that the facts are substantially the same as those determined by United States Circuit Judge Lorenzo Sawyer in the case of the Eagle Bird mine (*Francœur vs. Newhouse*), when, in 1890, he decided that lands not known to be mineral at the time of the grant were the property of the railroad company and not the Government, and title must be secured from the railroad. The Montana case was considered of such importance by the United States Supreme Court that a argument was heard by the full bench.

It is well known in California that the Central Pacific Railroad Company, backed by the Sawyer decision, claims all lands on odd-numbered sections within its grant not occupied at the time of the grant; in other words, it claims everything whose possession by some other at the time of filing its definite map of location was absolute and could not be disputed. This was in 1866. Therefore, the Central Pacific Railroad claims all mineral lands within its grant discovered since that time, nearly 30 years. The company has been fought bitterly for many years by various claimants, but without success. Under local conditions and local practice and decisions, it has become apparently firmly entrenched in this position, so that a claimant of mineral railroad lands has been compelled to secure title both from the railroad company and from the Government—a system, to say the very least, annoying, expensive and burdensome. The land offices have generally recognized the claims of the railroad company, and in many instances it is necessary to secure a quitclaim deed or other abandonment from the railroad company on odd-numbered sections before the land office will grant patent. The practice has been, in some instances, the same in Idaho, Montana and Washington, along the line of the Northern Pacific Railroad, the terms of whose land grant are much the same as to the Central Pacific Railroad.

It will be remembered that last fall, in this city, the United States Court of Appeals decided a case which in a measure controverted the Sawyer decision. It was entitled *N. P. R. Co. vs. Cannon et al.* Cannon had applied for and secured patent to mineral land on an odd-numbered railroad section. The railroad company then sought to have the issuance of patent set aside, on the ground that it was entitled to personal notice of the patent proceedings. The appellate court held that no special summons was necessary. The officers of the Land Office had given the usual formal notice by publication and post, and if the railroad company did not then interpose as contestant it was entitled to no personal notice thereafter. The court expressly held that "when appellant (the railroad company) accepted the (Government) grant, it knew that mineral lands were excluded from its grant, and the law charged it with notice that mining locations and applications for patents might be made, and patents obtained therefor by persons claiming the lands to be mineral." The railroad company therefore had the same right to contest as any other person or corporation, and no more. Having been charged to take notice of application for patent by the usual form giving notice to all the world, and having failed to avail itself of its opportunity, the question of the mineral character of the land became a question solely between the applicant and the Government.

This decision, if it does not in express terms declare, strongly implies that the railroad company's title to any mineral land is not valid. We have not heard, however, that it has altered the practice of the land offices or the claims of the railroad company in this State, though perhaps it has along the line of the Northern Pacific. It can be expected, however, that the much-disputed matter will now be settled by the United States Supreme Court.

IN answer to a question, it may be said that a prospector may take up as many claims as he desires, provided he follows the regular forms; and he can hold them by performing \$100 of work each year on every claim, or he may confine all the work to one claim, if they adjoin, and the development work is intended for the development of all.

California Mines at the Midwinter Fair.

Siskiyou County.—The conspicuous features of this exhibit are a collection of ores showing the variety and value of the county's mineral resources, and four cases of native and specimen gold, illustrating the purity and beauty of its gold product. The former are displayed in the space assigned to Siskiyou county, on a spacious table. No attempt at ornamentation has been made; but the various ores, gravels and other articles have been properly labeled, and attract attention from many visitors. The specimens were by the fair management considered of such unusual excellence that they were detached from the county exhibit and given a prominent place among a general collection of quartz specimens and native gold, near the center of the entire exhibit.

It is proper in this connection to mention Siskiyou's leading mineral characteristics, inasmuch as they present features which distinguish the county from others. As Placer is the home of drift mining, so has river and hydraulic mining an undisturbed abode in Siskiyou county. Its quartz mines are of value and, though the veins are as a rule narrow and the development in this direction comparatively limited, there is no reason to doubt that vein mining has a great future here. The presence of an ancient river channel is definitely known, having been traced continuously for nine miles from Henley to a point near Yreka; and undoubtedly drift mining will, sooner or later, be carried on there successfully.

The actual auriferous area of Siskiyou county is small; practically it is scattered over the western three-fifths of the county. There are six quartz-mining districts, three of which are generally termed the Salmon River district, but placers are widely scattered and cannot be so closely grouped.* For convenience, however, the mining districts of the county may be named as follows: Salmon River district, including the quartz and placers of the entire Salmon river drainage system; Callahan's Ranch, being the placers of the South Fork of Scott river; Quartz Valley, the quartz and placers of the valley of that name in the northwestern corner of Scott valley; Scott Bar, placers and quartz of the Scott river from where Mill creek joins it to its junction with the Klamath river; Klamath River, being the placers in the canyon of the river from Cottonwood creek to where the Salmon river comes in, including many old districts, unimportant now; Humburg Creek, the quartz mines on the several branches of Humburg creek east of Old Baldy summit; Deadwood, the quartz mines on the opposite slope of Old Baldy, and the placers of Indian and McAdam creeks, tributaries of Scott river heading in Old Baldy; Hungry Creek, quartz mines in that stream and on the headwaters of Cottonwood creek; Yreka, the quartz mines and placers near the city and Hawkinsville; and Henley, which might more properly be termed Blue Gravel. It is sufficient to mention the above as indicating in some measure the opportunities for quartz mining in the county; and to add that, with the exception of the Black Bear, there are no other very large mines. Siskiyou is, or has been, essentially a "poor man's" county. There is a great variety of small mines, and few large.

The chief interest in this county extends to its river mining and hydraulic and placer mining enterprises, mostly along the Klamath and tributaries, the operation of which has never been interdicted by order of the court. The method of mining along the Klamath, though often explained, will bear further elucidation. The Klamath is a crooked torrential stream, with tremendous flood stages, and a volume of flow only exceeded in the State by the Sacramento. The placers are the river bed for many miles, drift diggings in a few of the bars, notably at Hamburg bar, below the mouth of Scott river, and hydraulic placers, principally in the benches, some of them as much as 500 feet above the present river bed. The gold in appearance is very uniform, being a fine scale gold, smooth and water-worn. There is very little flour gold, and only a few claims produce nugget gold. The beds, bars and benches of the Klamath river, in the aggregate of 40 years of mining, have yielded an enormous amount of gold, and much yet remains in the unworked ground.

River mining on the Klamath is followed from about the mouth of Shasta river to Hamburg Bar. The claims are not as numerous as in former years, much of the ground being worked out and abandoned. Sixteen were being operated in 1892. The method of mining is the same in all the claims. Wing-dams are built of rock-filled cribs of poles, and faced inside and outside with inch planking. From 10,000 to 30,000 square feet of the river bottom is inclosed with these and cleared of water. A pit is sunk in this exposed river bottom; the top rock and sand containing no gold are removed by derricks down to

*A portion of the facts in the above review is obtained from the excellent article on Siskiyou county, by Russell L. Dunn, E. M., in the State Mineralogist's Report for 1892.

pay gravel, on and close to the bedrock usually, and the latter is then washed and the gold obtained.

Three current wheels are usually employed. A pump wheel, operating a Chinese or rotary pump; a bull wheel, which furnishes power to the hoist of the derrick, and a water wheel of much greater diameter than the others, rigged with buckets, which it lifts full of water to the head of the washing sluices. Occasionally the latter wheel is not necessary, water being taken directly from the river into a ditch and conducting it to the sluice. The fitting up of a claim, labor and material, costs from \$2500 to \$5000, and for the most part has to be all done anew for each season's work, though occasionally some of the plant is taken out of the river and above high-water mark before the flood stages of the river come and wash everything out.

Each claim employs from 10 to 40 men, working in two shifts, night and day. Pitch pine is employed for lighting the mines at night. The total expense of fitting up and operating each season is from \$5000 to \$8000. As a rule, the claims pay this back and something more in the way of profit, with a chance always of finding one of the very rich spots in the river from which the lucky miners may take out a fortune in a season's work. The Chinese are more and more acquiring a monopoly of this branch of the mining industry through purchase or lease of the claims from the white men.

The aggregate output per annum is about \$225,000.

The hydraulic mining industry of Siskiyou county has representation in a large number of mines, one or two of which it is worth while to mention. In Quartz valley the R. H. Campbell Gold Mining Company (limited) has 650 acres of placer ground and 850 acres of agricultural and other land covering the main watercourses of the valley, Shackleford and Mill creeks, for dump, site for drainage tunnel, and the heads of a ditch on Shackleford creek. The higher and shallower portions of the mine have been worked by the old miners and by the predecessors of the present company by ground sluicing and hydraulicking, the latter at one point assisted by an elevator. A considerable area, however, can still be effectively worked by hydraulicking, particularly in what is known as the Hull Gulch claim, the farthest up the valley. The area worked off by hydraulicking during 1892, the depth of ground being 35 feet, paid at the rate of \$25,000 an acre. Previous to the formation of the company, Mr. Campbell operated the mine by hydraulicking for ten years, about one month or less each year, taking out from \$15,000 to \$40,000 per year. The cost of the property altogether was \$100,000, the total sum realized over \$200,000. Without going into details, it may be said that the high ground is now comparatively limited in area and it will be necessary to work hereafter either by drifting or by elevators. A series of elevators is now contemplated. The water for this purpose is ample, being about 4000 inches. As it is now, the waste is tremendous, and there is generally insufficient water after August 1st; but it is designed to put in storage reservoirs, giving an equable flow as long as snow and cold weather do not prevent operations. These plans involve the expenditure of large sums of money and for that reason Mr. Campbell has enlisted ample English capital. The recent financial panic has for the present prevented the prompt development of the property on the lines contemplated.

In the Salmon river district, last year, occurred the greatest activity in Siskiyou county mining. A new road has just been finished from Yreka, via Etna, making the transportation of supplies easier and cheaper. Several new mills were erected last year, and more will probably be put up this year.

One of the recent successes in Siskiyou county has been the Greenham mine near Yreka, where a large placer deposit is being worked both by shaft and tunnel. The hoist and pump are worked by steam. The average pay is from \$250 to \$5 per yard, and about \$1000 per week is now being taken out.

The above is a very inadequate statement of the development of the fine mineral resources of Siskiyou county. The statements are called forth by the display at the fair, and may serve to indicate in some degree what is being done in the various branches of the industry. A partial summary of the articles displayed is as follows:

Specimens of gold ore from the Fairy Queen mine, the Golden Eagle, the Harrison, Spencer, Third Trial, Sterling, World's Fair, Tuscarora, Last Chance, Mammoth, Sergeant Brothers', Banner, Siskiyou, Mountain Belle, Punch Creek, Jassmond & Humphrey, North Star, Dale & Kiernan, Galena, Pennsylvania, Fagnones, Ahe Erno, Big Ledge, Grizzly Bear, Myers, Schroeder, Gold Run and Hunter, Empire, White Bear, Jumbo, Franks, Gold Ball, Boss and Hibernia mines; asbestos from the Salmon mountains; galena ore from the Humbug district; chrome iron, blue gravel and cement, soapstone, sandstone and petrified wood; a rock from the summit of Mount Shasta; pottery clay, granite, onyx, lead ore, copper ore, cinabar, agate, coal, gypsum and lime; a petrified pine burr, fossilized sandstone, dentritus (picture rock), four varieties; petrified clam; volcanic glass, or obsidian; Mount Shasta lava; galena, marble and limestone.

The Ashland Strike.

The strike in the Ashland mine, in Jackson county, marks an epoch in the mining development of southern Oregon. At a depth from the surface of 575 feet, a 600-foot tunnel has struck the ledge, thirty feet across the walls and carrying a good body of quartz. It is well known that vein mining in Oregon has always been confined to bodies of ore near the surface, depth never being attained. It was the opinion of many, and the practice of all, that the veins were not permanent, and would pinch out at a depth of a few hundred feet. Spotted ledges, pockety quartz and unreliable stringers were generally believed to be the characteristic features of the mines, and systematic deep mining was unheard and unthought of. It remained for the Ashland mine to make the first practical test of the character of the veins and to dispel prevalent theories about their superficiality. The mine was being worked by shaft, but the water so increased that it could not be banded. A drain tunnel was necessary. The experience and judgment of the operators convinced them that the ledge was permanent, and they decided to seek the ledge by a drain tunnel 400 feet below the 200 level. This course was unusual in southern Oregon, but the sound judgment of its projectors is amply justified by results. After 600 feet of dead work the ledge was struck in place. The future of the mine is absolutely assured. It cannot be doubted that the success of this enterprise will be a great incentive to more general and systematic development of other southern Oregon mines.

It should be added to the above that there is one other mine in southern Oregon which has attained a depth of 600 feet—that of Kubli & Bolt, in the Galice Creek district. The circumstances, however, were different. The vein, a narrow one, was followed in development. The mine is still being worked, the quartz being crushed in an old-fashioned arrastra.

Slitkens.

A COSTLY PLANT for refining borax is being constructed in Cottonwood canyon, Churchill county, Nevada. The works will produce 20 tons of refined borax monthly, and will give employment to about 20 men.

SOME prospectors recently returned to Campo, San Diego county, from the desert, exhibit fine specimens of gold rock, but are very reticent as to the locality of the find. They are preparing to return and open up the ledge.

THE Diamond Coal Company has been incorporated. Principal place of business, Los Angeles. Capital stock, \$20,000, with E. R. Kellern, R. C. Horton, P. W. Hoyle, M. Y. Kellern of Los Angeles, and N. Hoyle of Toro as directors.

THE Salt Wells Borax Company has been incorporated. Principal place of business, Independence, Inyo Co. Capital stock, \$2000, with Fredericke Rhine, Harry Rhine, F. E. Deusmore, Charles Ling and Wall Lee of Independence as directors.

THE mining camp of Kennedy, Nev., promises to be the banner gold-producing section in that State. There is some likelihood of a new railroad being built from Lovelock or some other point in the county to the copper mines in Churchill county.

THE *Critic*, a Johannesburg paper, offers a huge cake to the mine making, month by month, the best returns from its mine and mill. During January the cake was awarded to the Glencairn Company, of which Ernest Wiltsee, formerly of Grass Valley, is manager.

PLACER GOLD has been discovered within a mile and a half of Tehachapi and prospects well. From three pans of top dirt there was taken out 374 cents of the yellow metal one day this week. There are a number of men out prospecting and a rich find will not be a surprising event.

On Saturday, at Grass Valley, the annual meeting of the North Banner Consolidated Tunnel Company was held, 68,579 shares being represented. W. E. Brown and L. Gilson of San Francisco, and George Fletcher, J. F. Kidder and Joseph Weisshein were elected directors for the ensuing year.

At a meeting of the directors of the Morning Star Mining Company, held at the company's office in Colfax on Monday, April 23, dividend No. 40, amounting to \$3 per share, was declared. This is a regular monthly occurrence, and promises to be for a long time to come. The mine is looking as well as usual.

THE Sunrise Mining Company of Nevada county has filed articles of incorporation and named the following officers for the ensuing year: E. H. Baxter, president; George F. Hill, vice-president; D. J. Halloran, E. F. Baxter and J. P. Sweeney, directors. The mine is situated on Osborn Hill, 1½ miles south of Grass Valley.

It is now reported that Senator Wolcott of Colorado and Henry Wolcott have sold the Mercur gold mine in Utah to a party of New York capitalists for \$1,000,000. The new company will use electricity in the mine. The ore runs from \$8 to \$16 a ton. The vein is flat, eight to fourteen feet thick, and is worked like a coal mine.

CHARLIE ROSS (not the lost) was sitting in front of a stove at a Nevada City hotel the other day, when suddenly something exploded in his pocket. It was a giant powder cap which had probably been ignited by contact with a match. The side of Ross' vest was torn out and he received a painful wound in his hand, otherwise he is doing quite well.

THE siren at the Maryland mine, near Grass Valley, which takes the place of the old-fashioned whistle, is something new in this part of the country, says the Nevada City Transcript. It can be plainly heard in this city, and when the wind is

right the tones are like that of a huge æolian harp. Compressed air is used instead of steam to blow the siren.

CHARLES MARTIN came to San Bernardino last week and gave himself up to the authorities. He says that on April 5th, at a point about 40 miles east of Banning, he shot and killed a man named James in a dispute over the ownership of a mining claim. He claims that James and others jumped his claim, and in an altercation which followed he shot and killed James in self-defense. James was a resident of San Diego and Martin is of San Bernardino.

A DISPATCH from Cripple Creek, Colorado, April 8th, says: The miners had a stormy meeting to-day at Anaconda. President Calderwood of the Altman miners declared that the acceptance of the mine-owners' schedule would be suicidal to organized labor. John Wilson urged the wisdom of accepting, as miners had to work in other Colorado camps for \$2.25 to \$2.50 per day. The miners rejected with cheers the mine-owners' proposition of \$2.63½ per day of eight hours.

IN the Silver Star district, Esmeralda county, Nev., the Hard-scrabble mine, owned by Edward Brown, is said to be the best property there so far. To a distance of 35 feet he has a ledge four feet wide, the ore from which will average \$50 per ton. The Orphan Boy, owned by Douglass & Co., has a tunnel in about 60 feet and an incline 40 feet. The boys have on the dump about 20 tons of \$40 ore. The Julia, at a depth of 30 feet, is showing \$25 ore, and the Dollie, at 20 feet, \$20 ore.

A DISPATCH from Cripple Creek, Colo., says the greatest gold strike of the year at Cripple Creek is reported in the Caledonia. The mine is located with the vein, which is eighty feet wide. The lowest assay shows \$9 to the ton; a half-ton assayed \$100 to the ton. Several feet will run half that amount. Quartz streaks three to four inches wide will give as high as \$1000 to \$1500. The mine has been opened for two years, but attention has been called away from it and its richness was not dreamed of.

R. M. MACKAY, a California miner who has been mining in British Guiana, writes from Georgetown, under date of February 23d, to a friend in this city, asking him to advise Californians to stay away from that country. He writes that there is some gold in the colony, but that it is as much as a man's life is worth to go and look for it. There are a few rich alluvial mines that pay five and six pounds of gold per day to the long ton with five men working, but the average of the placers does not exceed two ounces of gold dust to the string of sluices with eight men working.

SOME weeks ago a miner named Wallace lost control of a windlass while hauling three miners up a shaft of the Helvetia mine, near San Diego, and they were precipitated to the bottom of the shaft. The men were not seriously injured and soon succeeded in climbing out of the hole. Wallace immediately disappeared, evidently crazed by the thought that he had caused the death of the men. No trace of him has been found since and fears are entertained for his welfare. He left a wife and six children in destitute circumstances. They have applied to the authorities for aid.

THE mine, furnaces and plant of the Oregon Iron and Steel Company, near Portland, Or., with the exception of the pipe foundry, have been leased for a term of years to Eastern iron-makers, who have sent an engineer to the mine purchased by the company some time since at Tepustete, Lower California, to superintend the building of wharves, bunkers, etc. As soon as a cargo of ore is received, the furnace will be lighted and about 200 men employed. As the ore from Tepustete is suitable for Bessemer steel it is the intention, after a time, to establish rolling mills in connection with the furnace.

A SPECIAL from Frisco, U. T., says: The new concentrating plant and hoisting works of the Horn Silver mine have been totally destroyed by fire. The mill made its first run on April 1st, but was not in operation when the fire broke out. The fire is supposed to have been of incendiary origin. The timbering of the shaft is on fire, and the ground is supposed to be caved in for a distance of 200 feet. Men were sent through the air shaft, but were unable to get near the main shaft on account of the smoke. All the miners were hoisted safely excepting six, who were compelled to climb the ladders through the air shaft from the 700-foot level. The loss is estimated at \$100,000. Operations will be resumed as speedily as possible.

It is reported from Boise, Idaho, that Benjamin Wilson has sold to J. C. Kempvance, representing a London syndicate, his placer lands in the vicinity of Pioneer, in the Boise Basin, near Boise. The consideration is \$300,000. The tracts sold aggregate about 2000 acres, the pay dirt being from 30 to 40 feet deep on an average. The sale includes over 100 miles of ditches and flumes and all the hydraulic apparatus belonging to the property. These claims have been worked for 30 years, and have produced a large amount of gold. The product is an unknown quantity, as no figures have been given out. Formerly the ground belonged to a number of companies, but all other interests were bought out by Mr. Wilson many years ago. He has since worked the property continuously.

THE Wolcott resolution for the coinage of Mexican dollars at United States mints has been passed by the Senate, and it will probably also pass the House. The full text is as follows:

Resolved, That the President of the United States, with a view to encourage and extend our commercial relations with China and other Asiatic countries, be required, if not incompatible with the public interests, to enter into negotiations with the Republic of Mexico looking to the coinage by the United States at the mints of a standard Mexican dollar under some agreement with the said Republic of Mexico as to seigniorage, method and amount of said coinage, and that he further report the result of his negotiations to the Senate.

GEORGE LOOMIS, the president of the Pacific Oil Company, owning large deposits of petroleum in southern California, and a well-known member of the mercantile community, died early on Sunday morning at the Menlo Park residence of his brother-in-law, ex-Senator Charles N. Felton. The deceased, who was born in Syracuse, N. Y., was sixty years of age. Mr. Loomis was well known for his enterprise in business affairs.

Gold Mines of Southern Oregon.

Written for the MINING AND SCIENTIFIC PRESS by Alex. Quartz.

Now that some of the southern Oregon mines are attracting considerable public attention in the East as well as on this coast, the following facts regarding the quartz-mining industry and its outlook may be of interest and value to those who are in quest of information relating to that section.

Ashland and vicinity—now the most prominent district in Jackson county—promise to become a prosperous and booming camp in the near future. The Ashland mine, which has paid good dividends continuously for the past year or more, has proven to the most skeptical that there is at least one permanent paying mine in that district. For years past, when speaking with mining men of the mines of southern Oregon and northern California, the majority of them said: "Yes, they all prospect well enough on the surface, but the mines don't go down in that section like they do in other places." To one and all I made the same answer. "The mines do go down, but it is the miners that don't go down." My opinion was based upon the knowledge I have of how most of the quartz mining and prospecting work in that section has been conducted until recently. A crosscut tunnel was run to cut the ledge in the Ashland mine at a depth of 600 feet, and various opinions were expressed by "the knowing ones" as to what would be found when they reached the ledge—if the ledge reached that depth at all. The ledge, which was cut a short time ago, proved to be 30 feet between walls, with eight feet of better ore than has been heretofore found in the mine, and confirms the theory that the ledges do go down in that section and carry the pay like they do in other places.

The development of a great ore body at a depth of 600 feet in a measure decides the future of the district. It will tend to give prospectors and capitalists more confidence in developing ledges which they were doubtful of before. There is one serious drawback to any district, that this strike in the Ashland mine may cause, and that is a raise in the price by those who have claims to sell, which will only serve to scare away capital and retard development work. The geological formation in the vicinity of Ashland is favorable for the existence of deep and permanent fissures and ledges—granite, slate and porphyry in well-defined belts being the principal country rock.

The Golden Fleece mine, situated three miles north of Ashland on the line of the Oregon and California railroad, is another property that is attracting considerable attention at present. This mine promises to become one of the largest low-grade gold mines in America, and, while in proportions it is like unto the great Treadwell mine of Alaska and the Homestake of Dakota, yet it is of a very different class, being similar to the Mercur mine of Utah. The reef or deposit is undoubtedly a portion of the prehistoric river channel that at one period drained the western slope, running parallel with the coast line, and is plainly traceable from the Umpqua river in Oregon to Trinity county, Cal., and on which there are several mines located and worked. The deposit, which is vast in extent, contains a curious combination of minerals, gold, cinnabar, native quicksilver and native amalgam all existing together in the same conglomerate mass. The deposit, or reef, which runs in an almost easterly and westerly direction, dips into the mountain side at an angle of fifteen degrees. The footwall, or bedrock underlying the deposit, is a porphyritic slate, cut in many places by seams of feldspar, carrying a large per cent of cinnabar, while the capping, which could be called the hanging wall, is a metamorphic sandstone. This metamorphic sandstone capping, in most places where it is opened in the mine, does not terminate abruptly where it joins the ore, but amalgamates with it where they join, so that it is in places difficult to determine where the sandstone cap ends and the ore begins. The ore underneath the capping appears to be a washed gravel cement, which gradually changes into an oxidized conglomerate mass of ore with little or no traces of wash gravel at the bottom. The present method of working is by an open cut into the deposit, and the ore, which is strongly oxidized by the presence of a large percentage of iron, pulverizes very easily, as high as one ton per hour being worked with a 3½-foot Huntington mill, using No. 40 slot screens. The gold, most of which is on the coarse order, is free in the ore or conglomerate, and all shows evidence of being wash gold at one time, though in its present condition it is heavily coated with iron and other minerals.

The general average of the assays and tests of the ore give a result of \$4 per ton. This mine can be worked, owing to its many natural advantages, cheaper than any mine on the coast. The present cost of mining and milling the ore on a small scale is about 65 cents per ton, ample water power for a large plant being available. The development of the mine on an extensive scale will be an im-

portant factor in bringing the mineral resources of southern Oregon into prominence.

A new ten-stamp mill is being erected on the "Shorty" mine on Wagner creek only a few miles from Ashland. As far as developed, this mine makes an exceptionally good showing, and will prove a good paying property beyond a doubt.

The placer mines of Jackson county have continuously produced gold in paying quantities since early in the "fifties," and if the generally accepted theory be true, that where there is a large number of good paying placer mines there must also be good quartz mines, there is certainly a good field for the prospector and capitalist in Jackson county, and especially on the slope of the Siskiyou range from Ashland to Jacksonville.

Although southern Oregon, and Jackson county in particular, which I visited recently, have been "black-eyed" and "cursed" by "natural gas" (?) capitalists and miners for years past, I firmly believe that in another year it will become prominent as one of the leading gold-producing sections of the Pacific slope.

ALEX. QUARTZ.

Mineral and Railroad Lands.

TO THE EDITOR:—It is necessary for the miners to have land to explore, on which they can get a valid title. This the miners in the northern part of California do not have. Here title must be obtained by purchasing mining claims on odd sections from two separate land offices. One purchase is made from the Southern Pacific land office, where the land is bought as agricultural land; and, again, the land must be bought at the United States land office in Redding, where the same land is sold as mineral. Each gives the miner what purports to be a title. Both titles have been sustained by the decisions of courts, while other courts have declared each void.

The railroad company's land office gives the miner a quit claim deed for agricultural land. The United States land office issues a mineral claim patent on the same land. A quit claim deed given by the railroad company on a section of mineral land can lie in hiding until some miner finds a rich mine on it; then, under Judge Sawyer's decision, the miner can be dispossessed, even though he has a Government mineral patent.

On the other hand, the railroad company's quit claim has in no case as yet merged into a title, and whether it ever will is very doubtful. The clause in their grant exempting mineral land must get some fearful judicial twists before the railroad company can give a clear title to land not given to them in the grant. There is a "pull-Dick-and-pull-devil" business going on between the railroad company and the United States land department, over mineral land, by which the miner suffers by every move either makes. The only chance that the people of California have of getting this land, if they do not want their mineral land to pass into the hands of a few men, is to have Congress appoint a committee to examine the land and report, stating the true condition, how this corporation is selling the mountains containing mineral as farming land.

Some time ago a complaint was made to the commissioner of the general land office that the Southern Pacific Company was selling mineral land, and a full statement was presented, with a request that some one be sent to make a report. This was sent to the commissioner, accompanied by affidavits. After some months of waiting, a long and wordy document was received in reply, with this farewell to it: "Your complaint is hereby dismissed for the reason that there are non-mineral affidavits on file on this land." Signed by commissioner general land office. The land referred to was that lying north of Redding on the Oregon line.

What the miners would like to know is, who filed those affidavits; who perjured themselves to let this railroad corporation sell mineral land? The mineral affidavits of the miners are on file in the Redding United States land office, and are open for inspection. If those non-mineral affidavits gave all the right the railroad company has to our mineral land (the commissioner's decision infers that) we would like to see whether they are true or not before some fair-minded court. The attention of our Congressmen, Senators and the next Legislature of this State will be directed to this wrong and may stop this duplicate land-office system and double titles.

The title to a valuable quartz mine must be perfect or no one will invest money in it. Under the system of this corporation, which was arranged to suit them, there is no telling where title begins or litigation will end.

Shasta, April 9, 1894.

JOS. E. BELL.

Mine Explosions Generated by Grahamite.

In a paper read before the American Institute of Mining Engineers recently, Mr. William Glenn drew attention to a somewhat novel cause of colliery explosions. The

Ritchie grahamite mines of Ritchie county, West Virginia, are situated near the central part of the upper barren coal measures of the Appalachian coal field. The rocks of the region are shales and sandstones, which lie almost horizontal. They show no evidence whatever of containing carbonaceous ingredients, except that they enclose, at long intervals, thin veins of exceedingly impure coal. The vein of grahamite is a straight and vertical fissure, which cuts downward across the horizontal strata of the rocks mentioned. Quite recently two explosions occurred in the mine, after shots had been fired, which could not be traced to gas, and which were clearly due to the ignition of fine dust.

The Nevada City Strike.

The first serious miners' strike in California for a long time occurred last Monday at Nevada City. For some time past the Harmony gravel mine has not been yielding enough bullion to pay expenses; in fact, there has been such a falling off in the monthly output that a portion of the directors were in favor of closing down.

Superintendent Gowell, who owns the controlling interest in the mine, proposed a reduction of wages from \$2.50 to \$2 a day. This was strongly opposed by nearly all the other directors and stockholders, the majority of whom favored the closing of the mine rather than bringing wages down any lower.

Mr. Gowell then himself decided to try a reduction of wages. A notice was posted at the mine to the effect that the wages of all the men underground, excepting drifters, would be reduced to \$2 a day.

The announcement was received with indignation by the 30 odd men employed in the mine, and all of them went out on a strike. Monday evening it was learned that four new men had been hired at the reduced wages.

At about 9 o'clock a large delegation of miners left town for the mine, which is situated on the Washington ridge, about 2½ miles distant. A number of interested persons went along to see what would be done. As they drew near the house occupied by Superintendent Gowell the lights inside were suddenly extinguished. A rap upon the door brought a response from Gowell, who inquired what was wanted. He was quickly informed of their mission, and replied that he would come to town in the morning and talk matters over with the strikers.

Proceeding to the mine, a short distance away, they ordered Foreman Hotherell to have the four men who were at work underground come to the surface. He complied with their request. When the men came on top and saw the crowd they became panic-stricken and made a rush for the woods. There was no boisterous conduct and no talk of violence—only a determined stand not to allow any one to work in the mine for less than \$2.50 a day.

Gowell arrived at Nevada City shortly before noon on Tuesday and was closeted with some of the directors for several hours.

After his conference with the board of directors, and finding that he would receive no support from them or the citizens in his effort to reduce wages, Gowell notified the strikers that they could resume work at the old rate.

Foundry Notes.

THE contract for building the proposed new tower on the city hall has been awarded to O'Connell & Lewie for \$249,700, their bid being nearly \$10,000 less than the next lowest. The only probable change in the specifications concerns the plates of steel which will cap the apex of the tower. It is not unlikely that these will be painted instead of electro-plated, as a saving of \$14,000 would be effected by the substitution. The entire work must be finished before the end of the calendar year.

J. K. FIRTH, the machinist whose financial troubles began last year, has asked to be declared an insolvent debtor. The indebtedness foots up the total amount of \$60,205.50. The assets of the petitioner consist entirely of personal property, valued at \$40,000, and encumbered for nearly \$30,000. The principal creditors of the insolvent, with the amounts due each, are as follows: Pacific Rolling Mill Company, \$1442.39, secured by transfer of contract with L. Bonet; Dunham, Carrigan & Hayden Company, \$376.62; Mrs. A. J. Kittredge, \$829; San Francisco Lumber Company, \$209.29; San Francisco Novelty and Plating Works, \$254.37; Joshua Hendy Machine Works, \$271.98; J. P. White, \$243.95; Crocker-Woolworth National Bank, \$3000 on a joint note of the petitioner and John Treadwell; J. G. and J. N. Day, \$3500 on a note; Fisher & Co., \$400 on a note; John Treadwell, \$1551.98 on a note; Wells, Fargo & Co., \$771.40; James W. Whiting, \$26,500 principal and \$2572.40 interest on a note secured by a chattel mortgage on machinery, tools, fixtures, etc.; W. P. Sullivan, Jr., and Oscar Lewie, assignees of other creditors, \$14,295.77; E. A. Belcher, attorney's fees, \$350. The insolvent's assets consist of personal property of J. K. Firth & Co., valued at \$36,350, bills receivable for \$3200.53 and personal property of J. K. Firth as an individual, valued at \$700. The firm property is encumbered by a chattel mortgage for \$28,606.98, held by James W. Whiting and referred to in the list of creditors. Firth claims property exempt from execution to the amount of \$400.

ASSESSMENTS on mining stocks amounting to \$294,420 will become delinquent this month, of which Nevada mines call for \$248,920, California \$20,500 and South Dakota \$25,000.

The Pyritic Smelting Process.

IN TWO PARTS—PART I.

By Philip Argall, E. M., in *Engineering Magazine*.

The greater part of the precious metals produced in the western United States are extracted from their ores by the smelting process, in which base metals are the vehicles used to collect the gold and silver contents of the ores and concentrate them in metallic lead, in a copper matte, and sometimes in an iron matte. The method of smelting employed in each particular case usually derives its name from the base metal used, or from the particular ore employed in the process of reduction; we have, therefore, so-called lead smelters, copper smelters, iron matte and pyritic smelters, though the principal object in each process is the extraction of the precious metals contained in the ores.

The Omaha and Grant Smelting Works at Denver, Colorado, may be taken as a typical example of a lead smelter, combining all the recent improvements. The output from these works for 1893 was: Lead, 20,865 tons; copper, 481 tons; gold, 90,213 ounces; and silver, 10,059,711 ounces, having a total value of \$11,917,828. Now the value of the lead in this output is but \$1,441,000, from which it appears that, for each dollar's worth of lead produced, over six and a half dollars' worth of precious metals were unlocked from the ores and started on their mission of usefulness to mankind.

The Boston and Colorado Smelting Works, also at Denver, is probably the best example of a copper smelter in the sense used in this article. The output from these works during 1893 amounted as follows: Copper, 5357 tons; gold, 61,102 ounces; and silver, 4,177,117 ounces, having a total value \$5,607,186. Of this amount but \$1,071,478 was derived from the copper or base metal used to collect the gold and silver ores. Here, then, we see that each dollar's worth of copper produced gave an accompanying value of nearly \$4.50 worth of precious metals.

Iron matte smelting, or the reduction of raw or partly calcined sulphide ores for the purpose of collecting the precious metals in an iron matte, though not much practiced in the west, has been conducted at various European works from a very early date. The German authorities show that one Barthel Kohler used this system of smelting at Frieberg as early as 1585. Dr. Percy, in his metallurgy of gold and silver makes special mention of iron matte smelting, and he shows that it is specially adapted to localities in which lead ores are not procurable at a sufficiently low rate to justify lead smelting. Such are the conditions that obtain at the famous Kongsberg mines, in Norway, and there iron pyrite has long been employed in smelting the ores. It is added to the furnace charge to the amount of 15 per cent of the ore smelted and serves to collect the silver in an iron matte, which subsequently is desilverized by means of lead. The furnaces used at Kongsberg prior to 1847 had a capacity of only 10 tons of charge per day. The pressure of the blast used was one-sixth of a pound per square inch, and the consumption of fuel in the furnace about 22 per cent of the weight of the charge, the fuel being fir and pine charcoal. Iron matte smelting has long been practiced at Sala, in Sweden, in Hungary, the Altai mountains in Russia, and in various other parts of Europe.

The first step in the Swansea method of copper smelting is the production of a copper matte, or copper-iron matte, in reverberatory furnaces, from the partially roasted ores. This is the method pursued to-day at the Boston and Colorado works, already referred to as a copper smelter. It will be seen that in all these matte-smelting methods, both for iron and copper matte, the ores, if sulphides, are first calcined to drive off the excess of sulphur, or, if not sulphides, then sulphur is added, usually in the form of pyrite (as in the Kongsberg practice, for example), in such proportion that the resulting matte shall form but a small part of the total product of the furnace—say 5 to 15 per cent of the ore smelted. In this way the precious metals distributed in the ores become concentrated in an iron or copper matte. When sulphide ores are to be reduced by the lead-smelting process, they are first calcined to drive off the sulphur, and thus convert the sulphides of the metals into oxides.

Pyritic smelting, briefly, is iron matte smelting in blast furnaces, but it differs from the ordinary matte smelting in the fact that, in the latter, no attempt is made to utilize the calorific properties of the ores, while in the former the aim is to perform the entire smelting operation in the furnace by means of the heat evolved from the combustion of the sulphides. To the lead and copper smelter, pyrites and other natural sulphides are not the most desirable ores, though valuable, it is true, for their iron contents, but nevertheless requiring calcination before they can be smelted, and therefore demanding a more expensive treat-

ment, which often results in a greater loss of precious metals than occurs in the smelting of oxidized ores.

To the pyritic smelter, however, natural sulphides, particularly iron pyrites, are not only docile ores, but are also fuel, capable of being consumed in the furnace, smelting not only themselves, but also the fluxes necessary to form a slag of the desired composition. Pyritic smelting, then, is intended to be a process of smelting without the use of carbonaceous fuel in the furnace. This at first blush seems impossible, and, though a theoretical examination of the process shows that it should easily be accomplished, yet in practice a small amount of fuel is often found necessary, particularly where the ores are not of the proper composition and character to give the best results.

It may not be generally known that pyrite can be burned in very much the same way as coal or other fuel, and that, when consumed under proper conditions, it can develop a temperature very little less than that produced by the best coal. Some persons who are, or should be, familiar with the combustion of pyrite assume that all the heat is derived from the sulphur. This is an error. The calorific power of one gramme of mono-sulphide of iron, Fe S , is, neglecting that absorbed by the dissociation of the elements, about 1621 thermal units, of which 807 are evolved by the combustion of the sulphur and 814 by that of the iron. The temperature produced by the combustion of mono-sulphide of iron is shown by calcination to be about 2200°C . Sulphide of zinc gives a temperature of about 2000°C ; lead sulphide, 1860°C ; while coal, containing 80 per cent of carbon, 5 per cent of hydrogen and 15 per cent of noncombustible matter, gives a combustion temperature of about 2700°C . It is important, however, to note that, while the combustion of coal apparently produces a higher temperature, in reality the sulphide of iron does more work in the furnace, for in the first case much of the heat produced is absorbed in expanding the gaseous products of combustion and associated nitrogen, whereas, in the case of sulphide of iron, the resultant product being mainly protoxide of iron, the heat generated is applied to a more essential purpose, the smelting of the ore. These facts are easily demonstrated by a calorific calculation, which the limits of this article will not permit.

It follows, then, that for metallurgical purposes these sulphides, particularly pyrite, can be made to act as fuel when the proper conditions for their thorough combustion exist in the furnace. Pyrite will burn under the ordinary atmospheric conditions, and give out considerable heat. The heap-roasting of pyritic ores is a familiar example. This process is conducted on an extensive scale at Sudbury, Canada, where large heaps of the miccoliferous pyrrhotite are set on fire and burn for considerable time, the object being to drive off the sulphur and prepare the ore for the subsequent smelting operation. At the pyrite mines in Spain heaps of many thousand tons are set on fire and burn for a period of five or six months, with the evolution of immense quantities of sulphurous acid gas. This practice will, however, with the introduction of pyritic smelting, be relegated to the oblivion of the barbaric methods of metallurgy; for, apart from the destruction of valuable fuel and the locking up of large stocks of ores for long periods of time, it also results in destroying the vegetation and soil, producing a general appearance of desolation and decay in the neighborhood of the works.

Tasmanian Mining.

Twenty-seven years have elapsed since the Tasmanian Government commenced the compilation of mining statistics, says the *Mercury*, the quantity of minerals raised in the colony during 1867 being put down at 1363 ounces 5 dwts. of gold, valued at £4381 16s. Up to 1875 gold was the only mineral raised in any quantity, but in that year, in addition to £11,982 worth of the king of metals, 490 tons of tin, 3200 tons of iron ore and 7719 tons of coal, the values of which were not recorded, were mined. The production of these minerals, with the exception of iron ore, went on increasing. In 1879 the zenith of the gold production was reached, 60,155 ounces, valued at £230,895, being then extracted. Since that period the amount produced has fluctuated considerably, the lowest point being reached with 23,451 ounces in 1890. Last year this was exceeded by about 14,000 ounces. In 1888 silver made its first appearance in the returns, the value of the 417 tons then raised being set down at £5830. One hundred tons of copper were also exported at that period. The production of silver-lead ore increased gradually till 1892, but in 1893 it took an enormous bonnd, the number of tons shipped from the colony being 157,710, with a gross value of £188,520. The maximum value of the Tasmanian mineral production was reached in 1887, when the total attained was no less than £761,683 from tin and gold alone, the value of the former exceeding half a million sterling. Last year, although the quantity of tin produced was but 792 tons less than that of 1887, the value of the metal, in consequence of deprecia-

tion, came in but £245,500, and the total value of the 1893 mineral production was £599,971.

Native Methods of Working Mexican Mines.

J. Howard Palmer, B. A., in *London Mining Journal*.

Mining has been carried on in Mexico since the conquest of the country by Cortez in the 16th century, and so robust and persistent are the veins in the Guanajuato, Zacatecas and Pachuca districts that the same mines have been worked uninterruptedly and at a profit for the last 300 years, and are still producing to-day. In countries like Australia or the United States, mining is a thing of yesterday, and every mine owner has to find out for himself how he can most cheaply mine and reduce his ore without having any experience of the past to guide him. The Mexicans, however, have been miners from father to son for centuries, and in the older fields at least, their practice both underground and on the surface is very economical and peculiarly suited to the conditions of the work.

All the principal mines are situated at altitudes varying from 6000 to 8000 feet above sea level, and, as may be imagined, at such altitudes fuel, water and timber are very scarce. There is hardly any coal in Mexico, except in the extreme north, and it is generally cheaper to burn wood in boilers. On the other hand, forage is cheap, as it only costs about \$1.50 per week to keep a mule, and the Mexicans accordingly get out of the fuel difficulty by using mule and horse power instead of steam, wherever they can. Instead of modern hoisting machinery, horse whlms, or malacates, constructed entirely of wood, are still largely used, and in the reduction works the Chilean mills and arrastras are turned by mules instead of steam power, and the same animals, when they are too worn-out for anything else, serve to trample and stir up the argenteriferous mud of the tortas. The ancient method of unwatering the mines is also very curious. All workings below the water level were so planned that they drained into a central sump or reservoir. Above this sump is fixed a barrel, over which runs and endless string of buckets dipping into the water below, and discharging into another reservoir 30 feet or so above the lower one. Suitable gearing actuates the revolutions of the barrel, and the whole concern is turned by a mule. Thus by a succession of these reservoirs and trains of buckets the water is finally lifted to the surface. These clumsy and expensive arrangements have, however, nearly gone out of use in the mines, though still employed for wells and irrigation. Great bags of ox hides sewn together and slung to the cable are now the usual means of unwatering vertical shafts where there are no guides, and tonneles, or cylindrical drums of wood and galvanized iron have also been found very efficient. These tonneles are generally about three feet in diameter and ten feet long, and are fitted with a valve lifting inward, so that they can be discharged automatically when they reach the top of the shaft. Steam and Cornish pumps are gradually coming into favor, and none too soon, for most of the old Mexican mines have now to cope with such quantities of water that powerful pumping machinery is an absolute necessity for further development. There are plenty of mines in Mexico where all that is wanted for profitable working is an economical method of dealing with the water, but it generally happens that the native owners are frightened at the expense of machinery, let the water rise and lose the mine. The worst of it is, that the Mexican engine drivers and firemen, from ignorance or carelessness, will not look after their machinery, so that breakdowns of hoisting gear or disastrous boiler explosions are far too common, and these accidents keep up the prejudice against machinery in the conservative minds of the Mexican mine owners.

The way in which the Mexicans often treat machinery is simply disgraceful, and it is not too much to say that many of their failures in deep mining are entirely due to neglect of hoisting or pumping plant. Inspection by Government authority has never been dreamt of, and the consequence is that boilers are allowed to choke up with scale, and leaky joints and burnt and pitted plates go from bad to worse until the inevitable disaster occurs. Then, of course, the unfortunate fireman is to blame, although with proper care and inspection the accident need never have happened. Another serious drawback to the employment of machinery in Mexico is the scarcity of skilled mechanics. If an engine or boiler goes wrong, the Mexicans are generally helpless to do the necessary repairs, and have to send to the nearest English mining company or railway for assistance. The fact is that the Mexican engineers are excellent miners in their way, but poor mechanics, and it is not to be wondered at that many mines are suffering from the reluctance of their proprietors to incur the risk and expense of the machinery necessary to set them going again.

It is in underground work, however, that the Mexicans exhibit their best, and though some of their methods are not perhaps so scientific as they might be, they are eminently economical and adapted to the conditions of the

mines. Adits are preferred to shafts, at any rate until the value of a lode is proved, for the Mexicans emphatically do not believe in sinking a vertical shaft through the country rock to cut a vein at so many meters down, however promising the outcrop may be, nor are they fond of driving an adit across the strike of a lode. The usual way of opening up a new vein is by driving an adit along the vein from the outcrop, of course as low down in the hillside as possible; when an ore body is found a shaft is sunk either from the level of the adit or from the surface, as the case may demand. Where hoisting is either slow or costly, shaft sinking costs from \$100 to \$200 per meter, against \$20 to \$40 per meter for drifting, and the Mexicans will not find the money for the former. When they do sink shafts, they are generally in payable ore all the time. If the configuration of the ground is unfavorable for an adit, they sink an inclined shaft upon the outcrop, always following the vein, with the result that the shaft gets as crooked as a dog's hind leg, if the dip is at all variable. They are by no means fond of working through country rock, but they will follow a vein forever, however barren and weak it may be, with wonderful patience. In Guanajuata especially, the lodes are very "pockety," and a small and disintegrated vein often suddenly widens out into a great ore body. In this district one tunnel was persevered in for 11 years, the vein being nearly barren during all this period. At last, however, when nearly a mile and a half had been driven, a bonanza was reached, producing more than a million sterling. In this case, at any rate, the policy of persistently following up the lode paid well. Some of these old Mexican adits are curious affairs. One that the writer remembers had evidently been begun 300 years ago, when the Spaniards first came into the country, when powder was too expensive to use for blasting. Just at the month there were still to be seen the traces of fires which had been lighted to crack the rock in lieu of blasting it, and inside were the relics of a tramway with wooden rails, which was probably older than Trevethick or Watt. With nothing more besides these primitive appliances, this mine in the last century produced \$30,000 to \$40,000 a week, nine-tenths of which would probably be clear profit.

Diamonds in Australia.

Albert F. Calvert, F. R. G. S., in London *Mining Journal*.

Owing to the number of reports that are at present being published as to the existence of the diamonds of Australia, a few words as to the fact may be of interest to your readers.

Referring to Mr. John Calvert's explorations in Australia in the early days, I am enabled to state that the diamonds of Australia owe their origin to three different sources, the oldest from the crystallization of carboniferous matter between the diorite or greenstone dykes and the quartzose reefs. This would take place near the surface and would, mostly, be long since denuded by the floods and rainfalls, being mixed with the detritus which has been washed down and accumulated from the higher lands. The second would be the overlapping of the basalts over the accumulations, formed by ancient river beds, and the heat of the basalts would be sufficient to make the conglomerates in which the diamond has been found, in many different parts of the world, more especially in India and Brazil. The last condition would be the extinction of some active volcano, the dying struggles of which would draw portions of the surrounding country into the vortex of the crater. The molten matter would then be partially thrown out, and, again and again being filled in, would at last settle down. The actual combustion ceasing, the fire would die out and a fresh set of circumstances set up. We should then have a huge basin filled with conglomerates, shales and schists, partially converted into clays more or less sprinkled with fragments of rocks of the surrounding country.

Now, the center of this accumulated debris would be of a lower temperature than the walls of the basin, which would retain their heat for some time. The hydrocarbons, which previously had been consumed, would now permeate throughout, and under pressure, together with the currents set up, the carbons would crystallize, and veritable diamonds would be the result. In Mr. John Calvert's field books he has several localities of diamondiferous conglomerates laid down, some accompanied by sketches of the districts. From his, and my own investigations, I consider Western and South Australia will give the richest and most productive mines, whereas Victoria, New South Wales and Queensland will come next in richness. The Bingara diamond fields belong to the second class, viz., the overlapping of the detritus of the ancient river (most likely the Horton) by the basalt. A portion has been denuded, leaving the diamonds in some parts practically on the surface, or within a few inches. This ancient detritus is composed of pebbles, white quartz, jasper, chalcedony, fragments of Devonian sandstones and upper Silurian shales, associated with rounded masses of corundum, sapphire, and black

tonmeline, also occasional zircons, and, very rarely, rubies and other precious stones; also magnetic iron with occasionally scales of gold adhering, and silicified fragments of various woods. These are occasionally interstratified with sand, and here and there beds of pipe-clay, and, where the basalts have been most active, patches of silicious or ferruginous conglomerate. Notwithstanding this tempting bill of fare I should recommend it with great caution to the speculating public, as, although the diamonds are indisputably there, yet there are many drawbacks and obstacles before the dividend would reach the pockets of the ever-confident shareholder. If he wants a veritable paying Australian diamond mine, let there be selected one of the pipes of the ancient craters, where the diamondiferous debris would be more largely impregnated with the glittering gem, and where the area of nature's operations is more concentrated.

Geological Maps of Mining Regions.

A Washington dispatch says Director Powell of the Geological Survey has turned the survey into a popular channel by planning a series of topographical and geological maps of the United States. Among these are maps of the gold belts of California, two of which are nearly ready for distribution. These are known as the Sacramento and Placerville sheets, and cover an area extending from the plane of the Sacramento valley to the foothills of the Sierra Nevada, a distance of nearly 40 miles.

To the gold-hunters of the West these maps will be of the greatest assistance. Their work at present is far from attractive. Although the annual output of gold in the world has been constantly increasing in the last eight years, that of the United States has decreased gradually since 1853, when it attained its highest figures—\$65,000,000. In 1892 the gold product of this country was estimated at \$33,000,000. The value of all the gold mined in the world that year was placed at \$130,817,000. Last year the world's product increased to \$146,000,000, but that of the United States is not far from the total of 1892.

The difficulties in the way of mining gold in this country have increased each year. In the early days of gold mining much of the precious metal was found in the beds of rivers and in rocks which had been forced to the earth's surface by volcanic action. On the western slope of the Sierras in California, where the original discovery of placer deposits in the United States was made, the topographical conditions were favorable to the concentration of gravel detrital material, resulting from the disintegration of gold-bearing rocks into hodies that could readily be worked by the aid of abundant water.

The increasing difficulty and the cost of gold mining in the United States drove the seekers after the metal away from the streams into the mountains. They had nothing to guide them but the experience gained in placer mining, and thousands of them eventually gave up the struggle. Some of them succeeded in discovering rich veins and in time capital came to their aid.

It will be seen that if these prospectors had possessed the information which the Geological Survey has now set out to provide, their task would have been far easier.

Instead of a haphazard search for gold-bearing rock, they would have been able to continue their search for wealth in a thoroughly business-like way. The most ignorant prospector would have been placed practically on an equality with the experienced metallurgist. The change in methods which this mapping of the auriferous deposits of the country will bring about is typical of the general change which has been taking place in connection with western conquests of the soil.

Observations on Ore Dressing.

Discussion by T. A. Rickard of paper read before International Engineering Congress by O. O. Bilharz on Ore Dressing.

The observations made by the author concerning the treatment of gold-bearing ores, deal with the subject only briefly and in a general way; but, coming from an authority, they invite comment.

In stating the fact that a "finely divided condition" is a necessary characteristic of ores containing free gold, the author must be referring to those mining districts only with which he himself is acquainted. The statement would not be true of certain gold-mining regions in America and Australia. The ores of some Californian mines and the mill-stuff treated at certain of the mills of Clunes and Ballarat in Australia, and of Otago in New Zealand, contain the gold in a free but in a coarse state. Moreover, "reduction to fine sand and flour" is not required by certain ores, even though the gold be in a finely divided condition. In such cases the ore becomes detached from the quartz before the gangue has been pulverized into particles as small as that in which the ore occurs.

The dry crushing of free-milling gold ores is unknown in

the new mining regions of the world. It is not clear whether the author has in mind any European district in which such a process is in actual use. If he has, a description of the method and results obtained would be very valuable. Dry crushing is, other things being equal, twice as slow and twice as expensive as wet crushing. In the case of free milling gold quartz it serves no purpose, since such ore does not carry sulphides which contain any large percentage of value, and which, by being slimed, may carry away part of that value. The dry crushing of a free-milling gold quartz would be considered an absurdity by an American metallurgist.

If the ore contain "free gold only," why submit it to a further treatment, such as concentration, after its passage over the amalgamating plate? What does the author propose to concentrate?

Coming to the consideration of the treatment to be given to ores containing the gold in close association with metallic sulphides, the author requires that it be treated by successive stages. He probably refers to crushing with rolls. As a general proposition, it would seem to me that the reverse is more nearly true, and that crushing is to be avoided as far as possible, as tending immediately to make slimes, the formation of which is the most potent cause of the loss of gold. Why anticipate the treatment of tailings by the MacArthur-Forrest or some other process? The satisfaction felt by a mill man in saving gold by a subsequent treatment of the tailings from his mill appears to me to be like that of the man who shoots at a rabbit, and having missed with the first barrel, gets it with the second. The one is no proof of good marksmanship, neither is the other of good milling.

Road Drainage.

At the Good Roads Congress held in Chicago in October, J. J. W. Billingsley read a paper upon the subject of Drainage which in the main is correct when he says:

Among those who have given the subject of road improvement careful attention, there is settled conviction that the good condition of any road depends upon a system of thorough drainage—a system which embraces not only the removal of the storm water which falls upon the surface of the road and the land adjoining, but also the water which filters through the ground. The latter, if allowed to percolate into and through the subsoil underlying the roadbed, will render the travelway soft and springy, often affecting the compacted surface of the road so as to cause it to break up, or, in other words, "the bottom drops out."

In fact, the basis of all road improvement in this country is the thorough drainage of the road surface and the foundations of the roadbed. In the experiments which have been made in road drainage by laying one or two lines of tile drains along the sides and parallel with the road, the result has been so satisfactory that some persons have become enthused with this method of road improvement and conclude that in it there is a remedy for all the defects which may be encountered. But we are convinced that the best improvement of our highways will combine at least three essential features, which are:

A road embankment of sufficient height to be at least above overflow from extraordinary rainfalls and sufficiently crowning to shed the water readily and wide enough to accommodate the travel, and not of greater width; that the road shall have open ditches on each side of sufficient capacity to carry all flood-water from the roadway and from the lands adjoining into the nearest water course; the surface or open ditches should have such a perfect grade that no water will find a lodgement along the line of the road on either side and that two lines of tile drains be placed parallel with the road, one on each side, at the base of the embankment.

The underdrains should be laid at the depth of three or more feet. The size of the tile will depend on the length of the drain and the fall, but it is probable that they should not be less than four inches in diameter in any case, and as much larger as the needs may require. The three essential features named embrace two systems—one the removal of the surface water speedily and effectually, the other the removal of the water of saturation remaining after the removal of the surface water, and the prevention of the flow of soil water under the roadbed. The underdrains should have a uniform descent or grade to some natural stream or outlet where the water discharged will flow away freely and at no time back up in the drain. The crowning of the road should be sufficient to cause the water falling upon the surface of the road to flow readily to the side ditches. If it fails to flow away, and remains in the ruts and depressions, it will increase the amount of mud and the inconvenience of travel. Roads in such a condition should have road machines passed over them as often as necessary to make the roads level.

It is a mistaken idea that an underdrain laid in the

middle of the road will drain the surface of the road. The travel and the action of the water falling upon the road will so effectually puddle the surface that no water on the road will find its way down to the drain thus laid. To the contrary, the horse tracks and ruts will hold water like earthen vessels until it is removed by evaporation or otherwise. Roads graded and drained as proposed will cost from \$400 to \$500 per mile, but when done they will be good roads for eleven months and commendably passable the remainder of the year with a little timely repair. Where gravel and stone are not to be had at a reasonable cost, we know of no improvement so satisfactory in all respects as

tile with gravel or sand a few feet, so that surface water may pass down freely into the underdrain to prevent its accumulation where it is likely to affect the road embankment.

After a road has been put in good condition and thoroughly underdrained, nothing need be done except a little timely repair in the way of keeping the surface smooth and the open ditches free from any drift accumulation. Road drainage has passed the experimental stage. The benefits have been fully proven. The success of the improvements depends only upon the thoroughness of the work. A few suggestions as to the construction of the underdrains may

that no more important duty lies before us to-day the effect of which will be more widely felt than that of giving material aid and to otherwise encourage the permanent improvement of our public highways.

A Walnut Elephant.

One of the unique features at the Midwinter Fair is the Los Angeles walnut elephant, in the Southern California building. It stands on a platform 12 feet square and 15 feet high, with supporting wings six feet square and eight feet high, representing a triumphal arch. The archway is

THE LOS ANGELES WALNUT ELEPHANT AT THE MIDWINTER FAIR.

the road well graded and sufficiently drained. Where gravel or broken stone can be had, it will be found that the thorough drainage of the road, as proposed, will save half the gravel or stone that would otherwise be required to make a good road. A dry foundation to build upon is the most important factor in road construction. Tile drains may be used to intercept water percolating through the earth of the higher ground adjacent and likely to interfere with the road, or springs or seepy places under the roadbed may be drained out with tiles so as not to interfere with the embankment. It may be found advisable at some points along the line of the drains to fill in above the

he helpful in this connection. One of the most important features of a good drain is a desirable grade—one free from depressions below or rises above a true grade line. These conditions, it has been remarked, are never secured without effort; slight depressions will fill with silt sooner or later, and so far destroy the efficiency of the drain. The tiles should be laid in a trench carefully fitted for them, and so carefully settled in their bed that the filling of the ditch will not displace them, and the joints should be closely joined; and if any difficulty is experienced from quicksand, the covering of the joints with clay will prevent any trouble from this source. In conclusion, we remark

supported by four glass jars, 36 inches high, and filled with varieties of citrus fruits, representing pillars or columns, the interior of the arch and the outside of the whole structure are covered with 15,000 oranges of the best quality of Washington navels. Upon this structure of oranges, lemons and other fruits stands this life-size elephant. It is an astonishing piece of work, and the task of placing 1000 pounds of walnuts on the skeleton of the animal to form his hide is realized to have been a very tedious one. The saddle-cloth, howdah and trappings are outlined in citrus fruits, peannts and corn; the passenger is a young lady of wax.

Mechanical Progress.

Manufacture of Pins.

The machine that makes pins turns out 75,000 of these tiny essentials in an hour. Before the pin is finished it goes through very many different operations, which are described in the *Youth's Companion* as follows: A reel of wire hangs over the machine, the free end of which passes between two rollers.

As the wire leaves the rollers it passes between two matched dies until it touches a gauge. Just as it does this the dies come together and clamp it firmly in a groove in their face. At the same time the machine cuts it off the proper length.

The gauge then moves away, and a little punch forms the head by striking the end which rested against the gauge. When this is finished, the dies separate and deliver the pin into one of a great many grooves in the face of a wheel about a foot in diameter, as wide across its face as the pin is long. When the pin is taken by the wheel it has no point; but as the wheel turns it rubs the pins against an outside band, which causes each one to roll in its groove, and at the same time carries them past a set of rapidly moving files, which rub against the rough ends and sharpen them roughly.

They next pass against the faces of two grinding wheels, which smooth the points, and then to a rapidly moving leather band having fine emery glued on its face. This gives them the final polish; and as they leave the band they are dropped into a box underneath the machine.

After this the pins are plated with tin to give them a bright, silvery appearance. They are prepared for plating by being first immersed in weak sulphuric acid, to remove all grease, and then dried by being placed—a bushel or so at a time, with about the same quantity of sawdust—in a machine called a tumbling barrel.

This is simply a cask suspended on a shaft, which passes through it lengthwise. Two or three hours' rolling in sawdust cleans the pins and wears away any little roughness which the machine may have caused.

Pins and sawdust are taken together from the barrel and allowed to fall in a steady stream through a blast of air. The sawdust being the lightest, it is blown over into a large, room-like box, while the pins, being heavier, fall into a bin below. After this they are spread out in trays having sheets of zinc in their bottoms, which have been previously connected with one of the wires of an electric battery. The trays are then placed in a tank containing a solution of tin in muriatic acid, and the other wire of the battery is inserted in the solution. Electrical action immediately begins, and deposits metallic tin on the entire surface of each pin.

They are then washed in a tank of water and put into other tumbling barrels with hot sawdust. When they have been dried and cleaned of the sawdust, as in the former instance, they are put into a large, slowly revolving copper-lined tub, which is tilted at an angle of about 45°. As this revolves, the pins keep sliding down the smooth copper to the lower side. This constant rubbing against the tub and against each other polishes them.

It was the practice formerly to allow pins of all lengths to become mixed in the different operations, and after polishing to separate them by a very ingenious machine; but it has been found more economical to keep each size to itself.

From the polishing tub the pins are carried to the "sticker," where they fall from a hopper on an inclined plane in which are a number of slits. The pins catch in these slits, and, hanging by their heads, slide down the incline to the apparatus which inserts them in the paper.

As the number of pins in a row on the paper and the number of slits are the same, an entire row is stuck at once by an ingenious device, which takes one pin from each slit and inserts them all at once in the two ridges which have been crimped in the paper by a wheel that holds it in place to receive the pins.

At the same time this wheel crimps the paper it spaces the rows so that when filled with pins the paper will fold up properly.

This whole machine is so delicate in its action that a single bent or otherwise imperfect pin will cause the machine to stop feeding until the attendant removes it; yet its operation is so rapid that one machine will stick 90,000 pins an hour.

As the long strip of paper on which the pins are stuck comes from the machine, it is cut into proper lengths by girls, who then fold and pack the papers in bundles ready for shipment.

How to Silver Glass.

I have frequently noticed, says a correspondent of the *Scientific American*, under the heading "Silvering Glass," various silvering solutions, such as are used in the plating of mirrors; and as I have tried each one of them myself and attained results far from satisfactory, I beg to send herewith formula for a silvering solution which contains only a small percentage of silver compared with others which I have unsuccessfully tried, and which will invariably produce excellent mirrors, provided the following conditions are adhered to:

1. Pure chemicals.
2. Have the glass chemically clean.
3. Adhere strictly to the formula.

And I trust that readers who have been endeavoring to silver glass with the other solutions heretofore given will advise you of the superiority of the following:

1. *Solution.*—Dissolve $2\frac{1}{2}$ drachms nitrate of silver (crystals) in two ounces of water, and add concentrated liquid ammonia, drop by drop, until the brown precipitate formed is nearly, but not quite, all dissolved; then add 24 ounces water and filter three times.

2. *Reducing Solution.*—Dissolve $1\frac{1}{2}$ drachms nitrate of silver in 24 ounces of water; then take one ounce of water in a graduate and dissolve in it 30 grains white caustic potash, and add this to the 24 ounces of solution just mentioned; then add 420 grains Rochelle salts. Filter three times.

Note.—Solution No. 2 will be found to have a heavy black precipitate, and it is necessary to filter same until it is perfectly clear, which can be accomplished by having three funnels one above another, with filtering cotton packed in rather tightly.

Use distilled water.

To use the above solutions, mix equal parts of No. 1 and No. 2 together, and flow over the glass, which, however, must be in a room heated to about 90 or 100 degrees F.

We have tested the formula printed above and find that it gives excellent results. Two parts of No. 1 to one part of No. 2 by measure gave better results than equal parts. The glass should be cleaned with caustic potash dissolved in water and should be thoroughly rinsed before silvering. The process of silvering can be hastened by having a steam table on which to lay the plate of glass over which the combined solutions have been poured. A gas stove or an oven may be used. Small pieces of glass can be silvered in one to two minutes by holding them a few inches above the flame of a Bunsen burner. Defective spots may be remedied by removing the silvering around the spot with nitric acid and resilvering. If the hands become stained with the solution, rub the stains with a crystal of resublimed iodine until the color begins to change, then sponge with alcohol. Only small pieces of glass should be attempted at first until the method of working the process is well understood.—Ed. Scientific American.

Production of Color in Glass.

The beautiful coloring of certain varieties of glass now produced in Germany, and which far excels some of the most noted French specimens, is, according to *Die Glashutte*, accomplished by the glassblower at the furnace, by means of an apparatus consisting of a sheet-iron cylinder, 20 inches long and 8 inches diameter, standing vertically and having a similar cylinder riveted across the top, thus forming a T-shaped muffle. In the lower cylinder is an opening into which an iron ladle can pass, and the horizontal cylinder is provided with doors at either end, the one nearest the operator being so arranged that the blowpipes can be supported when the door is closed in a horizontal split running to its middle, the object to be treated being held inside. While the glassblower is reheating his work for the

last time in the furnace, an attendant takes the long-handled iron ladle, which has been heated red hot, shakes into it about a spoonful of a specially prepared chemical mixture, and places the bowl of the ladle quickly in the opening provided for it in the vertical cylinder. The mixture immediately gives off vapor, which rises to the horizontal cylinders, where meanwhile the blower has placed his work, supported by the blowpipe, and heated to an even red, turning it rapidly in the vapor. In a short time the object is covered with a changeable luster, is removed from the pipe and tempered like other ware in an ordinary oven, then cut, engraved painted or gilded, as desired.

In a ton of Dead Sea water there are 187 pounds of salt, Red Sea 93, Mediterranean 85, Atlantic 81, English Channel 72, Baltic 18, Black Sea 26, and Caspian Sea 11.

STAMP MILLS.

VULCAN WIRE ROPEWAY

for Conveying ORE, CORDWOOD, ETC.

SNYDER MINE, KENNETT, CAL.

In reply to inquiry as to how Tramway is doing, am prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.

It will give us great pleasure to recommend your Ropeway and your Company as well to any persons who may be thinking of erecting Ropeways.

VENTANAS M & M Co. VENTANAS, MEX.

We take pleasure in testifying to the successful operation of the Vulcan Wire Ropeway furnished us by your company. It easily transports the required quantity of ore from mine to mill and has given us no trouble whatever.

VULCAN IRON WORKS.
135-145 Fremont St., S.F.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with the shaft. SPECIAL CONSTRUCTION OF STEEL only one-eighth part the weight of the old pump. Works with 10 per cent less power. First outlay one-third less. Suitable to any underly or downright shaft. Occupies less space in the shaft. Has been tested a year and proved to work satisfactorily in every respect. GLAND OF STUFFING BOX, TIGHTENED AND ROD LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING OR BUCKET PUMP.

Bucket, clack and clack-eating changed under water. Bucket lasts six times as long as the old bucket, often saving expense of putting down another pump, especially in jack-head pumps, where bucket and clack cannot be changed under water. Special attention is called to the self-tightening stuffing-box and new bucket which obviates the expense and delay of frequently dropping extra pumps.

Scientific Progress.

Was There a Flood?

One of the largest meetings ever held by the Victoria Institute of London, England, took place in the third week of March to hear that well-known "Nestor among Geologists," Prof. Prestwich, F. R. S., read a paper on "A Possible Cause for the Origin of the Tradition of the Flood," in which he proposed to treat the subject "from a purely scientific standpoint." The chair was taken by the ex-president of the Royal Society, Sir George Stokes, Bart., F. R. S., the present occupant of that professional chair at Cambridge University once occupied by Sir Isaac Newton, and also the president of the Victoria Institute, whose aim is to investigate all scientific questions bearing on the truth of the Bible, and to associate all scientific men, and people generally, in the colonies and America, in aid of this work. The business was commenced by Capt. F. Petrie, the honorary secretary, reading a letter from the Duke of Argyll, who was unable to be present, after which Prof. T. Rupert Jones, F. R. S., read the paper prepared by Prof. Prestwich, he not being sufficiently recovered from a severe cold to do so himself. In it the author described at considerable length the various phenomena which had come under his observation during long years of geological research in Europe and the coasts of the Mediterranean. Among these he specially referred to having found the flints of the drift to be of two classes—one with bones of animals, carved, and interspersed with the remains of man, and the other, which he termed the Rubble-drift, containing bones of animals of all ages and kinds in vast heaps. He cited the confirmatory opinions on this point of Prof. Geikie, F. R. S., a member of the Institute, and drew special attention to the geological surroundings of these strange deposits and the manner in which the bones were found. He then referred to phenomena in regard to raised sea beaches, and the constant occurrence of "head," the large masses of transported rock, loam and loess, covering the high plains in Hungary and southern Russia, and the ossiferous breccias in various localities.

From the circumstances attending these and their surroundings, he said he had been forced to the conclusion that all their phenomena were "only explicable upon the hypothesis of a widespread and short submergence followed by early re-elevation, and this hypothesis satisfied all the important conditions of the problem," which forced one to recognize that there had been a submergence of continental dimensions. The age of Man was held to be divided into Palaeolithic and Neolithic, and he considered rightly so. He concluded by suggesting that thus there seemed cause for the origin of a tradition of a flood.

The paper was followed by reference to a communication from Sir W. Dawson, F. R. S., who welcomed the paper as confirming his conclusion come to on geological and palaeontological grounds of a physical break in the anthropic age. The evidence of this was afforded by the cave remains and from a vast quantity of other sources. The discussion which ensued was commenced by Sir George Stokes, Bart., F. R. S., referring to the great value of the author's contribution to our knowledge and right understanding of the phenomena he had so long studied. Among those present were Mr. Haddleston, F. R. S., the past president of the Geological Society, and Dr. Woodward, F. R. S., the present president. The latter proposed a cordial vote of thanks to his friend and teacher, Dr. Prestwich, "the Nestor among Geologists," whose contributions to our knowledge of that science were recognized by all as greater, more far-reaching and more valuable than those of any other in the present century. After

sundry other remarks, Sir Henry Howorth, Bart., F. R. S., spoke, urging the the great importance of recognizing the value of the arguments in the paper and many others which had come under his own observation in Asia. Prof. McK. Hughes, F. R. S., of Cambridge University, followed with some criticisms, and bore warm testimony to the value of the paper, after which Prof. Hall, F. R. S., late director of the Geological Survey of Ireland, spoke strongly in favor of the scientific nature of the author's arguments. Prof. Rupert Jones, F. R. S., in a few sentences replied to the speakers, and the gathering dispersed.

Leonard Smokeless Powders.

The ingredients of the Leonard powder, according to the patent specifications, for the United States 30-caliber rifle are given as follows:

150 parts by weight of nitroglycerine.
50 parts by weight of gun cotton,
10 parts by weight of lycopodium.
4 parts by weight of finely triturated urea crystals,
but the proportions are varied according to the caliber of the gun which is to use it.

If dinitrobenzol be employed in the manufacture instead of finely triturated urea crystals, a similar quantity, namely, four parts, should be used. The several ingredients named above are first mixed together, and there is then introduced as a solvent either acetone alone or acetone combined with acetic ether. The solvent is evaporated by agitation, and the material is formed into a cake or granules by pressing in molds. The analysis of cordite, which we give for the sake of comparison, is as follows:

Gun cotton as previously used at Wallbam Abbey	37 parts
Nitroglycerine	58 "
Vaseline	5 "
Total	100 "

The solvent here used is again acetone, the proportion being 19.2 parts. The mixture is incorporated for three and one-half hours, and is then squeezed into threads. If the "scouring" and "pitting" actions which accompany the use of cordite are obliterated in the "Leonard" powder, the *Scientific American* thinks a bright future is before it.

The Geologic Age of the World.

Prof. C. D. Walcott expresses the opinion—contrary to that entertained by some scientists—that geologic time is not to be measured by hundreds of millions of years, but simply by tens of millions. This is widely different from the conclusion arrived at by Sir Charles Lyell, says the *Scientific American*, who, basing his estimate on modifications of certain specimens of marine life, assigned two hundred and forty millions of years as the required geologic period; Darwin claimed two hundred million years; Crowell, about seventy-two millions; Geikie, from seventy-three million upward; Alexander Winchell, but three million, while McGee, Upham and other recent authorities claim from one hundred million up to six hundred and eighty million. The data presented by Dr. Walcott, showing the distribution of geologic time, or the different periods of sedimentary rocks, give two million nine hundred thousand years for the cenozoic and pleistocene, seven million two hundred and forty thousand for the mesozoic, seventeen million five hundred thousand for the paleozoic, and a like period to the latter for the algonkian—a total of forty-five million five hundred thousand years.

Nicotine in Tobacco.

Dr. G. B. De Toni, Venice, has published the results of histochemical researches on *Nicotiana Tabacum* and other species of the genus. He finds the alkaloid, C₁₀H₁₄N₂, to be located chiefly in the epidermal tissues. It is absent from the seed and the young plant. In the root of the mature plant it occurs in the cortical tissue, and especially in the layer of cells immediately beneath the epidermis. In the branches, leaf stalk, lamina of the leaf, peduncle, calyx and

corolla it is almost entirely confined to the epidermal cells, and occurs especially in those at the base of the hairs. It is found also, in smaller quantities, in the anthers and pistil. The mesophyll and assimilating tissue of the leaf gave uniformly negative results. Nicotine does not appear to exercise any protective influence on the tobacco plant, since both the fresh and dried leaves are devoured by many insects. The author believes its function to be simply excretory; it is a product of the reduction of oxygenous substances. The following are given as the best chemical tests for nicotine: The double iodide of potassium and mercury; iodized iodide of potassium; tannic acid; tetrachloride of platinum; iodized iodic acid; Dragendorff's reagent; trichloride of gold.

THE

English and American Mechanic

AN EVERY-DAY HAND-BOOK FOR THE WORKSHOP AND THE FACTORY.

Containing several thousand Receipts, Rules and Tables indispensable to the Mechanic, the Artisan and the Manufacturer. By E. Frank Van Cleave. A New, Revised, Enlarged and Improved Edition. Edited by Emory Edwards, M. E., Author of "Edwards' 900 Examination Questions and Answers for Engineers and Firemen." Illustrated by 85 engravings. One volume, 500 pages, 12mo, closely printed; the matter covering an extremely wide range of useful technical information for all classes of mechanics and other practical men.

A circular of 24 pages, showing the full Table of Contents of this valuable book, will be sent free and free of postage to any one in any part of the world who will furnish us with his address.

Pig Lead, Nickel and Aluminum Alloys,
Patent Smelting Furnaces,
Metal Furnace Condensers, Banxite,
Aluminum Reduction Works,
Gold and Silver Concentrating Plants.
We will take entire charge of the work from foundation up, including construction of buildings, erection of machinery, turning the entire plant over to you, under steam, and in running order. We have special experts in our employ for that purpose. Cash advanced on silver-lead concentrates and lead slag shipments.
Buyers, Smelters and refiners of car lots of ore.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$8.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulas as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

TUBBS CORDAGE CO.
(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order upon short notice.
611 & 613 Front St., San Francisco, Cal.

Electricity.

Electricity for Heating.

In a paper by W. S. Hadaway, Jr., a short time since, he says:

A well-designed central station of moderate size produces a horse-power hour by the combustion of about three pounds of good coal. The electrical horse-power hour developed by this coal has 2565 heat units; we have to balance these 2565 heat units in the concentrated form against 42,000 heat units existent in the three pounds of coal in a more diffused state, and determine whether, for heat purposes, the difference in the form of the energy, with its enormous attendant losses, compensates for the energy lost in bringing the heat units of coal into the higher form of energy capable of economical transmission to a distance.

It is found in practice that the commercial efficiency of the coal-cooking range is somewhere between three and six per cent; these limits are stated by Tyndall. In a recent discussion before the London Society of Engineers, Nov. 6, 1893, Mr. Beaumont gives the efficiency of the cooking range from experiments of his own as 3.7 per cent, or, roughly, four per cent, indicating that of every 27 pounds of coal burned, 26 pounds are thrown away. We have seen that the heat efficiency of the average moderate size central station is about six per cent. There is sufficient margin between a heat efficiency of 3.7 per cent and one of six per cent to warrant the use of electricity as a source of heat in domestic life, and a further extension with apparatus of larger size and higher working economy would give a still greater margin between coal burned under the boiler and that used in the firepot of the range. Thus with the use of only $1\frac{1}{2}$ pounds of coal per horse-power hour he would secure a commercial efficiency of 12.2 per cent, or 3.3 times the efficiency of the range.

At the outset, of course, the cost of electrical energy as fuel under average conditions at the power rate will be greater than fuel directly burned. But there are compensating advantages gained which more than offset the additional cost. This has been abundantly proved in actual practice. The saving of attendance and of time, freedom from dirt, coolness of the kitchen, absolute uniformity of heat and ability to regulate it, appeal at once to the householder. There is merit aside from novelty in such practice.

In industrial work, wherever flames are used to secure localized heat, electricity can be advantageously employed. It is more easily regulated than flame, there are no unhealthy products of combustion, the mean temperature of the shop is lowered, the temperatures are constant, the work is more uniform, and the entire system cleaner and more complete. For factory use it is the most desirable form of fuel. In laundries, clothing manufactories, hat factories, silk and all textile fabric mills, shirt factories, rubber-goods manufactories, furniture factories, etc., are good fields for the use of electricity for heating. In domestic life no source of heat offers so many elements of value as the use of electricity for cooking and laundry work. There is no discomfort, no noxious gases from combustion, and the temperatures attained are constant, so that the question of the discretion of the cook is eliminated, and better results obtained than can possibly be reached from the approximate temperatures of surfaces heated by combustion. It may be fairly stated that people who could afford to do their lighting by electricity could afford to do their cooking and ironing by the same means.

Electricity for heating will be found of the same value to central-station electric-lighting companies as the use of gas for fuel purposes has proved to the gas-lighting companies. Its value lies largely in ability to localize the heat, and it will not be found

desirable to use it on a large scale where diffused heat is wanted. High temperatures and small quantities are the proper uses for electricity for fuel.

Perpetual Lightning.

The phenomenon known as lightning, followed by a rolling, reverberating report, recognized as thunder, is common to a wide zone of the earth, but it is not generally known that there are localities where the vivid flashes and the deafening peals are incessant, says a technical exchange. The most notable of these continuous lightning districts is on the eastern coast of the island of San Domingo, a leading member of the group of the West Indies. It is not meant that the lightning is here continuous the year round, but that, with the commencement of the rainy season, comes the zig-zag feature of the electric illumination, which is then continuous day and night for weeks. The storm center is not continuously local, but shifts over a considerable area, and, as thunder is seldom heard over a greater distance than eight miles, and the lightning to the night will illuminate so as to be seen 30 miles, there may be days in some localities where the twinkle on the sky is in a continuous succession while the rolling reports are absent. Then again come days and nights when the electric artillery is piercing in its detonations, and especially is this the case when two separate local cloud centers join, as it were, in an electric duel, and, as sometimes occurs, a third participant appears to add to the elemental warfare. Then there is a blazing sky with blinding vividness and stunning peals that seem to pin the listener to the earth. Long before the echoes can die away come others, until the auricular mechanism seems hammered into chaos.

Just how and why it is that there is here generated so immense an amount of electricity as to keep up such an incessant ignition is one of those problems that can only be solved when sufficient data are at hand to work upon. It is probable that, with the commencement of the rainy season, this region is the border of opposing air and ocean currents whose friction has something to do in the case. This would tend to bring into contact opposing clouds variously charged, and as lightning is the passing of electricity from one cloud to another, seeking equilibrium, or the passing of the fluid from a cloud to the earth, it is probable that, in this continued friction of currents, may be found a starting point to unravel the mystery. It is in swirling and opposing cloud strata, especially where these get into gyratory motion, that electrical phenomena are most abundant, just as, in an even, uniform flow of clouds, such disturbance is rarer and often entirely absent.

Artificial Light Without Shadows.

B. A. Dobson, at a recent meeting of the Institute of Mechanical Engineers, London, read a very interesting paper upon the best method of artificially lighting workshops and other places where the incandescent lamp is a too expensive form of light and where the arc light, as ordinarily used, is unsuitable on account of the sharp shadows it casts. To sum up his paper in a few words he found that the most satisfactory results were obtained by reversing the current in an ordinary arc lamp, producing a crater in the lower carbon and projecting the light up against a whitewashed ceiling from where it was diffused throughout the room, instead of the usual method of producing the crater in the upper carbon and projecting the light downward directly upon the work from the very small point of illumination offered by the electric arc.

The plan suggested by Mr. Dobson is by no means a new one, and the sun lamp, invented many years ago and extensively used in Paris, worked on a similar plan. In this lamp carbons were placed at an obtuse

angle on top of a block of marble and the arc played across the surface of the stone, producing a light similar to the calcium light used for theatrical effects. The marble was opaque and the light was projected against the ceiling and the room was filled with a soft yet bright light somewhat like daylight. The old sun lamp would be regarded as a pretty bad lamp nowadays, for mechanically it was imperfect, but any one who remembers seeing it in operation cannot but think that a better application of the same principle will some day solve the problem of interior illumination by the arc system.

Useful Information.

A Precaution Against Consumption.

It is now pretty well established that tuberculosis is an infective disease, and if this is true, it is largely preventable. We believe that in this country especially there is not sufficient stress laid upon the communicability of consumption; the people are too apt to regard our climate (southern California) as Nature's panacea. Phthisical patients fairly swarm upon us every winter, poisoning our hotels, our streets and our dwellings. The inspissated sputum retains, according to Sawisky, its virulence two and a half months. Here, since the advent of the ooe-lunged Yankee, children die of meningitis and youth of consumption. This we are told by some to regard as the unfathomable dispensation of a wise Providence, when it rather should be charged to the criminal negligence of an easy-going public.

Persistent and systematic precautions ought to be taken by both public officials and the people in general to stop this scourge. The health department should issue stringent orders, classifying this disease among those usually placarded.

The room occupied by a consumptive should receive as thorough a disinfection as the one used by a diphtheritic patient. If the phthisical patient died within a week or two, the quarantine should be demanded and carried out. If the public really thought consumption "catching," they would regard it just as natural to take precautions against its spread as it is to stamp out leprosy. In point of fact, there is no comparison between the contagiousness of these diseases—tuberculosis being much more communicable. A campaign of education is needed.

All tuberculosis patients should be compelled for the public good to use spit cups. Public spittoons filled with sawdust or other matter easily combustible should be placed at convenient intervals. The American has been described as a spitting animal, but he must be trained to spit by law only in specially prepared receptacles. The old college saying, "Those who expectorate on the floor cannot expect to rate as gentlemen," should be impressed upon all.

Then, again, the dust of the streets ought to be removed frequently, but only after a thorough sprinkling. Public hospitals for the tuberculosis poor ought to be established. In the present state of affairs only a very few of the worst cases are treated—while thousands wander about the city polluting the very air with the germs of the greatest scourge that has ever afflicted mankind.

Hygienic treatment should be advised in all cases. Preventive medicine is no longer the medicine of the future, but the medicine of to-day. Let us follow the example of Michigan, and officially declare consumption a contagious disease. Another point of great importance is the denying to consumptives the privilege of engaging in occupations whereby they may endanger the life or health of others.

The sanitary inspection of cattle and condemnation of tuberculosis cows should be

rigidly enforced. Indeed, did our government take half the interest in preventing disease among human beings that it does in looking after the health of hogs and cattle, there would be thousands of lives saved annually.—Southern California Practitioner.

Effect of Fire on Concrete.

Concrete is often used as a fireproof building material, and as such, says the *Architect and Builder*, is commonly considered a safe material for walls or foundations which may be built for that purpose. A few experiments will demonstrate its unreliability in that respect. Take a piece of dry and hardened concrete work, such as is used in walls or foundations, and break it into three parts or lumps, leave one in its original state, and place the other two pieces in the fire, where they should remain at a light red heat for five to fifteen minutes, according to size; then remove both pieces, place one to cool naturally and the other in water to cool. When cold and removed, it will be found that the one naturally cooled will crumble easily and the one cooled in water will crack and fall apart with very slight pressure.

Some two years ago we had an experience with concrete walls, where the interior of a two-story building had been destroyed by fire. We recommended that the walls be taken down and rebuilt; but it was decided to repair them. Where the fire was light, but little damage was done; but near the base of the walls, where the hurroing braods had fallen and the fire generated the greatest heat, was a strip all round that had crumbled away, leaving the walls at this point only about half their original thickness. The most pronounced of the disintegrated concrete work was cut out and brick work built in; soon afterward the exterior portion of the walls showed signs of giving away, whereupon sections were cut out and built in with brick. As time passed, the walls in the other portions also began to show the disintegrating effect of the fire on the concrete work.

We wish more particularly to direct the attention of the officers of the various fire departments to the danger which may attend concrete work, especially where the basement or foundation portion of the walls has been built of such material, and which in turn supports brick walls, three or more stories in height.

In many cases the concrete work is placed where the fire and steam together will tend to weaken the support, and in a moment, without warning, the walls may come tumbling down over the firemen, repeating the horrors frequently depicted by the press.

Making Paper Adhere to Metal.

A recently discovered method of making paper adhere to metal is so successful that after application it is next to impossible to remove the smallest portion of the paper without entirely destroying it, says the *Optician*. The invention is particularly adapted for the purpose of fitting metal plates at the back of lithographs, engravings, and designs of various kinds, additional value being given to it by the fact that atmospheric conditions cannot affect it.

Experiments have proved that all acids possess the properties necessary for this purpose, though varying in degree, but the best agent is hydrochloric acid mixed with an equal quantity of water to which has been added a little oxide of zinc, added immediately after the effervescing action has taken place. The plate of metal is coated with this compound, and after being dried carefully is covered with fine coach varnish. So prepared, the plate is placed in a drying oven with a temperature of about 30° C. for say 20 minutes—by this time the varnish will have almost entirely lost its adhesive power. Carefully place the sheet of paper intended for use on the prepared surface and

submit it to strong pressure. The result will be adhesion of the most perfect kind. The method may be applied with advantage to mounting colotype blocks by a pellicular process.

Drift Mining at Yankee Jims.

Yankee Jims was once famous for its rich mines. As is known to most of our pioneer residents, the district was mined principally on the surface, says the *Colfax Sentinel*. In some places it was fabulously rich and nearly everywhere the surface paid. Afterward, when mining was carried on extensively by the hydraulic process, several large mines were worked. Owing to the high banks and the extensive amount of clay and cement in the upper strata, many of these mines had to be abandoned, at least for a time. It was not because there was not gold there, but because there was so much non-paying material that had to be worked up with the pay dirt if the gravel was mined by the hydraulic process. A few years after being closed down came the warfare on hydraulic mining, and of course the abandonment became more effectual than ever.

Within the past years, although gravel has been found in so many of the mines in the vicinity, these old hydraulic mines have received but little attention. They have been looked upon generally as worked out because of the fact that the district is an old hydraulic district. A reporter of the *Sentinel* visited some of these old mines last week and was quite agreeably surprised at the prospect still in view. In one place is a line of old hydraulic pits up against the mountain side, abandoned because of the great height of the banks and the futility of working it by the hydraulic process. Here is a bank of gravel with a face of 3000 feet and extending back at least 3500 feet. Many of the claims have been lying comparatively idle for 20 years, owing to various causes. A few short tunnels have been run occasionally and some very rich gravel has been struck, but the tunnels have been too high and the water has prevented their being worked. As most of the mines have been held by parties abroad, they have received very little attention.

It is claimed by all the old pioneers about the place that the mines will pay to drift. To justify the necessary outlay for running a bedrock tunnel, putting up a mill, etc., the mines should be consolidated into one. There is every opportunity for gaining ample water power with the natural supply of water in the vicinity. The location is convenient, and the section all about there has paid well. The Mayflower mine is only about 1½ miles distant, and the Cranage and Federer mines are only a half-mile away. Last winter some very rich gravel was struck within a quarter of a mile of the mines mentioned.

It strikes us that some day out of these old hydraulic mines will grow a good drift mine, just as has been done at so many places on the Forest Hill divide. If no reasonable prices are not asked, no doubt capital could be induced to prospect these old mines, and Yankee Jims become famous in the future for drift mining as it was in the past for surface mining.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the slides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

BOOKS ON ASSAYING.

BY C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in each plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Ore; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Mixing in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Course Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.
The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by **DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.**

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Niter.
One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.
Price, postpaid, \$1.75. Sold by **DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.**

Curious Facts.

Corsets have been found on the mummies of Egyptian princesses of the royal family.

Lobsters have a great dread of thunder, and when peals are very loud will swim to deeper water.

The owl's wise look is the result of a physiological oddity, his eyes being fixed immovably in their sockets.

Humboldt describes an oak tree which he saw in France, which was 90 feet in circumference at the base and was estimated to be 2000 years old.

The city of Glasgow, in Scotland, has a multitude of low-legged and knock-kneed children, made such by an almost exclusive diet of potatoes, they not getting bread, which contains the elements which stiffen and strengthen bones; and the same lack occasionally produces the painful specimens of rickety hunchbacks to be found in American tenements.

The lion is a formidable-looking beast, and his imposing appearance and great strength have caused him to be crowned the "king of beasts." But for all that, he is really inferior in muscular power to some other members of the same family. The strength of his fore limbs is said to be only 69 per cent of that of the tiger, and of the hind legs only 65 per cent.

The Congress of Norwegian Physicians, which recently met at Christiana, instead of hiring a hall, held its meetings on a large steamer which moved from place to place, so that they had fresh air and change of scene while they were holding their deliberations. Thus they were hygienic as well as scientific, and possibly less depleted in purse than if lodged in hotels.

The loftiest scientific station in Europe is Sonnblück's Observatory in the Austrian Alps. The keeper, Peter Lechner, has hitherto led a hermit life, but has recently found a peasant girl who will share his lofty and silent abode. The wedding took place at a village at the foot of the mountain, and among the wedding gifts were presents from the Emperor and from several native and foreign scientific societies.

A process of plating aluminum has been devised by Prof. Neesen, a German chemist, which shows very good results. The aluminum is first dipped in a solution of caustic potash or soda, or in murlatic acid, until bubbles of gas begin to appear, then into corrosive sublimate, then a second time into the caustic or acid, and finally into a solution of a salt of the desired metal. A film of the metal is rapidly formed, and adheres so firmly that, in the case of gold, silver or copper, the plate may be rolled out or polished.

Manufacture of Fulminate of Mercury.

An improved method of making this dangerous explosive is as follows: Ten grammes of mercury are dissolved in the cold in 120 grammes of nitric acid (sp. gr. 1.45). When the solution is complete and the liquid cold, this liquid is poured into a flask containing 110 grammes of alcohol (95 per cent strength). Action soon begins, without the application of heat, and is allowed to develop and then cease naturally. The mass is then treated with water until no longer acid, and when it has been slowly dried, it is ready for use.—Scientific American.

NEW METHOD

Of Roasting and Smelting different kinds of ores has been successfully demonstrated, and is now being introduced with unprecedented success. The slow and cumbersome methods heretofore employed will be discarded, and the cost of various ores in treatment or conversion into metal, greatly reduced. All the matte of the latter, which was heretofore sent to Germany, is now being refined in the United States.

All questions on metals, ores and their practical method of treatment readily and conclusively solved. We are prepared to erect Reduction Plants, for same, and run them successfully for any length of time, to be agreed upon by contract.

Why experiment when you can have a certainty? Correspondence solicited.

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

FRANCIS SMITH & CO.,

MANUFACTURER OF

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

NO. 180 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

MINE OWNERS!

ELECTRIC TRANSMISSION OF POWER GUARANTEED.

REFERENCES GIVEN TO PLANTS IN SUCCESSFUL OPERATION.

Upon receipt of necessary data, we will furnish complete specifications and estimates.

Electrical Engineering in all its branches, and Construction Work undertaken.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

A NEW INDUSTRY.—*Livermore Herald:* Messrs. Pitcher and Taylor last year paid out in other places for the crushing of their manganese and chrome and other ores nearly \$3000. They have decided that Livermore might just as well have the benefit of this and have concluded to erect a mill here. It is now in process of erection on the lot adjoining the electric works. A shaft will be connected with the engine in the electric works and the power obtained from it. About 60 tons of manganese are now dumped there ready to be crushed. The prospect of a large yield from the mines is good.

Butte.

PLACER MINING.—*Oroville Register:* Placer mining in Butte was at one time a very important industry, but this kind of mining gradually declined until now the shallow surface mines are but slightly worked. In place of these deep gravel mines have been found, and these give employment to many men and each year yield a good deal of gold.

The most famous of these mines is the Perschbaker, near Magalia. It is owned by N. D. Rideout of Marysville, and is without doubt one of the richest gravel mines in the world. Owing to its great depth and the immense quantity of water that has to be handled, it is a very expensive mine to work.

At Gravel Range several companies are working excellent channels beneath the lava rock. Near Nimsbaw and on Botte creek are very profitable gravel mines.

About Lovelock, Yankee Hill and Nimsbaw are numerous good mines.

At Enterprise gravel mining continues to pay well.

Bangor is at present the center of the most extensive gravel mines in the county. Here five or six large mines give employment to many men. The gold is found in a very hard blue cement which has to be blasted and then be ground on like rock ere it will yield its precious metal. Gravel mining is steadily increasing and the output of gold grows larger rather than smaller each year.

Calaveras.

AT THE BOLITHO.—*Angels Echo:* William Osborn is again at work driving the tunnel into the hill on the Bolitho mine. This is in some respects a very remarkable mine. The ore body into which the tunnel is being driven is 43 feet in width, at a depth of 100 feet. The ore contains about five per cent of rich sulphurets and increases in richness as the tunnel is driven ahead.

RICH STRIKE.—*Angels Echo:* A rich strike has recently been made in the Blair mine, near Smith's Flat. The rich discovery was made on the 200-foot level, where the vein is over 12 feet in width. The Blair mine is a splendid piece of mining property and gets richer as depth is attained. We understand that it is the intention of the owners to sink the shaft a hundred feet deeper. When this mine is thoroughly developed, it will be second to very few mines in this county as a gold producer. It is said that \$1600 were taken out of the Blair mine in a single day recently.

AT CAMPO SECO.—*Sentinel:* There is a strong effort being made in Lodi to form a mining company to operate near Campo Seco. It is a well-known fact that there are some good mines there, both quartz and placer, but by reason of the rebellious condition of the ore and the fineness of the gold in some places, it has been a difficult task to make it pay to operate there heretofore. Now, however, new patents and inventions have been brought into use, and ore that could not heretofore be worked to any advantage at all can now be profitably handled. Capitalists are turning their attention to these abandoned gold fields, and by reason of the low price of products many others are leaving the farming communities and prospecting in the mining districts. Campo Seco is near at hand and easy of access, and parties looking for investments in this way would do well to look over this section before going elsewhere. D. B. Nye, of Campo Seco, writing from there a few days ago, says he has mines that he would be willing to guarantee would pay from the start, if a small amount of capital could be secured to start with.

Kern.

THE GOLLA FIELDS.—*Kernville Cor. Visalia Delta:* In addition to the number of men who have lately come into the mines here, several parties have gone through for the Goller region. No very great portion of the gold there can ever be extracted until a canal shall be brought in from Owens river above the lake. This would cost all the way from \$200,000 to \$1,000,000, owing to the size of the canal. The "dead river" channel into these gulches is in some places filled with 1000 feet of silt.

El Dorado.

NO HARD TIMES.—*Democrat:* Thomas Stevenson informs us that mining matters are holding their own in his neighborhood, despite the cry of hard times, and that at the Johnson & Hadley mine, near Spanish Dry Diggings, they have been running ten stamps since last June profitably. They are now running a tunnel, and if the present indications are verified the owners intend to erect a new 20 stamp mill.

LOCATOR A MINE.—*Green Valley Cor. Republican:* George Leach & Co. of Colorado have located a quartz mine in our neighborhood. It is the north extension of the Meder mine. The

owners have sunk a shaft 70 feet deep and propose to continue to the depth of 200 feet to prospect the ore body. They have four men employed and have built a house on the ground. They are using a windlass to hoist with at present.

Aylmer, Patton & Co. are cleaning up their ground on Gray's Flat. It is a gravel deposit about 14 feet deep which they sluice off during the winter by rain-water caught in reservoirs. At present they are shoveling the bottom dirt into sluices and employ about six men. Their average daily clean-up is said to be 12 ounces.

Humboldt.

FROM MOREK HILL.—*Blue Lake Advocate:* Mr. W. G. Miller has received a letter from Mr. A. B. Campbell, one of the stockholders in the Morek Hill mine, announcing that operations have been resumed and telling of the progress made. The letter says in part:

I have burned nearly all the timber that was down when you left, also what slid in, and have cleared south and east of the mine about one and a half acres, burning everything cleared. I have burned nearly all the timber on the west that was down and intend to cut and burn all the timber to the prairie on the west and up the little creek on the west. I first set the giant about fifty feet in front of the point under where you last set it and about ten feet to the east, and piped from seventy to a hundred feet into the lower end of the mine, within about eight or ten feet of bedrock. Then we found so many had stamps wedged into the cut that I decided to take them out through the new cut.

We began on our last set of the giants at noon to-day. We developed the heaviest wash southeast of where our giant sets now that has ever appeared in the mine. So heavy was it that Stokes noticed it this morning as soon as he came into 'the mine. "That is the heaviest wash I have ever seen here," said he; "regular river holders." He tells me you found nothing like it last year.

We have a small cut now where the new opening will be and I don't think we are fifteen feet at the outside higher than the bedrock cut at the mouth and no sign of bedrock yet. * * * We manage to keep the pipe going all the time and haven't lost a day or an hour yet on account of the weather. * * * We tried a digger ranch fireplace but it smoked so we built a regular old-fashion fireplace.

A postscript dated later announces that the crew had "struck bedrock top just about as high as month of sluice and we piped three feet deep in it this eve."

Mariposa.

AT THE WAAN.—*Gazette:* Considerable machinery is being brought from San Francisco for the Ward mine. Barleigh drills are to be used, and there is talk of a 40-stamp mill being built immediately. This mine is one among the best in the county, and we will all be pleased to see it fully developed.

Orange.

ANOTHER COAL MINE.—*Santa Ana Blade:* L. M. Cox, R. C. Cotton and J. W. Pither have located a coal mine in the Hamilton canyon, an offshoot of the Trabuca. A paying vein of coal is already in sight, and the prospects are good for the development of a valuable property. A force of miners will be put to work at once to open the mine and get out coal. The coal is pronounced by experts to be of good quality. There is no doubt that the Santiago range has many good veins of coal, and it is only a question of time when it will be worked in quantity.

Nevada.

THE MAAFIELD.—*Transcript:* A small force of men were put to work on the Merrifield mine Monday. As soon as more men can be worked to advantage the force will be increased. The Merrifield is owned by the Champion Company, and they intend to open up and thoroughly prospect it, believing that there still exists in the lower depths valuable ore shoals that have never been touched.

MINING AT ROUGH AND READY.—*Tidings:* Henry Schroeder was up from Rough and Ready on Saturday and he reports that lively times are expected in the mining line at that camp this season. Men are at work cleaning out the shaft at the Osceola mine, which is under bond to Messrs. Moody and Gayety of Placer county, who have rehoned the mine to a company of San Francisco capitalists. These latter are expected here next week, when the erection of machinery on the mine will be commenced. The Mistletoe mine is still turning out good ore, as is also the mine belonging to the Dunstan Bros. of Grass Valley. The ore from these mines is not free-milling and has to be smelted, and it is said that a joint smelting works may be erected this summer near Rough and Ready to treat the ores from the different mines in that section.

THE MERRIFIELD.—*Transcript:* Charles E. Uren, county surveyor, to-day completed a full survey of the Merrifield mine property, which belongs to the Champion Mining Company. A large two-compartment shaft, 16 feet wide, will be sunk, commencing about 40 feet above the present shaft. New hoisting works will be put up and other necessary buildings erected, the lumber for which is already on the ground. Work will be pushed ahead as rapidly as possible, but it will be some time before many men can be put to work. As soon as the shaft is down deep enough to start a level, and the mine begins to be opened up, as large a force of miners as can be worked will be employed. The company means business and intends to open up the mine in a thorough and systematic manner.

AT THE CONLAN.—*Telegraph:* Mr. O'Connor, the superintendent of the Conlan mine, informs us that work on that property will be resumed immediately. The company intends to

see that excellent prospect to its utmost limit, and no means of development will be spared. It is on Osborn Hill and that is enough.

CLEAR OF WATER.—*Union,* April 6: The Granite Hill mine was entirely pumped out at 2 o'clock yesterday afternoon. The full force of men will be at work Monday and Superintendent Waggoner will push work as fast as possible.

TO BE STARTED.—*Union:* The Eastern Star mine on the Johnston ranch, southeast of town, owned by City Marshal Dennen and others, is to be started up this week.

A HYDRAULIC MINE.—*Union:* James Hackett of Rough and Ready has been granted a permit by the Debris Commission to work a couple of claims by the hydraulic process. The working of these claims will give employment to 20 men. As a small head of water will be used, it will require about two years to exhaust the gravel deposit. Other residents of Rough and Ready feel encouraged and will soon make application to hydraulic their claims.

BLOOMFIELD MINES.—The new quartz mines are making work and business for North Bloomfield, and in the event of their turning out well they will be a big help to the town, says the Nevada City Herald.

The Busy Bee claim keeps several men at work, and a contract is to be let for sinking a new shaft.

The White Diamond Company has put in a pump, and they now work two shifts in sinking their shaft.

The Bloomfield mine has put on a few more men lately, while the Derbec has reduced its force.

Placer.

STRUCK THE LONA.—*Sacramento Bee:* J. B. Patterson of Newcastle, formerly assemblyman for Placer county, was in the city lately. He says his mine near Newcastle is showing good results. They have tunneled in 300 feet and have struck the mother lode. The rock pans out now over \$20 per ton. Mr. Patterson says there is no stock for sale.

MUCH LUMBER.—*Colfax Sentinel:* The South Yuba Company has received 24 carloads of lumber for the flumes in this section. In all, the lumber amounts to over 200,000 feet, and is the largest shipment recorded here for a long time. The large pipe to be used in crossing Long ravine will be here in a short time. The company is making rapid headway, and the contractors are putting the "finishing touch" on their respective jobs. They are driving a tunnel near the Long ravine bridge, through which the pipe line will run for a short distance. The cuts for the pipe are all completed, and from now on the work will be very rapidly pushed.

Riverside.

THE GOOD HOPE.—*Riverside Press:* Col. Egan of the Good Hope mine, near Perris, says work is progressing at the mine very satisfactorily, and when the stamp mill is in place it will be one of the finest appointed mines in the whole country. It is expected to have everything ready for pushing the work of milling the ore by May 1st. The mine, when it came into the hands of the present owners, was down 350 feet. It is now down 550 feet, and proves better the deeper it goes. Col. Egan says that a number of the miners with families are building homes, and that the class of men he has brought with him is of that kind that make good citizens, many of whom having been engaged with him in mining matters for the past 18 years.

San Bernardino.

GOON MINES.—The Tingman and Holland mines, located about 20 miles north of Indio, are still yielding gold in paying quantities, and give promise of greater development. Tingman's mill has been crushing ore for Lang & Son, but as soon as he can arrange for water, Mr. Lang will put up a mill.

A MILL FOR CRASOENT.—*Vanderbilt Shaft:* A. F. Stevens arrived in Vanderbilt on Monday, being on his way home from San Francisco, where he went to purchase a stamp-mill for the Legal Tender Mining Company, of which he is superintendent. The mill, which will be here by April 15th, is a Fulton Iron Works five-stamp mill, the stamps weighing about 900 pounds each, and will drop five stamps 100 times per minute. Although but five stamps will be put in at first, there will be power for 10 stamps, and the mill will be fitted for that number. Frue Vanner concentrators will be used. The mill is to be erected at Crossmen Springs, 3½ miles from the mines. The haul from the mines to the mill will be all the way down hill, however. The mill building will be 25x75 feet, and will be built of Arizona lumber. Besides this, there will be erected an engine room 20x30 feet, an office 12x24 feet, an assay room 12x14 feet, and a dwelling house for Mr. Stevens. The head carpenter will be Mr. Stevens' brother, E. C. Stevens, who came down from San Francisco to take the position.

CONSIDERABLE WATER.—*Shaft:* The Bronze is producing considerable water at present; in fact, the amount produced is increasing daily, and by the time that the shaft has been sunk another 100 feet the company will have little need of the water from Willow Springs, with which the stamp mill is now supplied.

The mill is working to perfection. All the kinds of ore thus far tried have been satisfactorily worked, and there is no doubt that the mill will accomplish all that was claimed for it.

THE BOOMEZANG.—Mr. Campbell is now erecting a steam hoist at this mine. He has been intending to do this for some time, but was hindered because all his mechanics were on the mill. The hoist will be in operation very soon, and it is probable that the shaft will be sunk to the 500 foot level at the rate of a foot per shift, the shifts being eight hours. The vein is looking splendid at the bottom of the shaft, being as strong and as well defined as ever, although

it is below the point at which, it has always been claimed, the vein would quit. The vein has never looked more promising than at present.

As soon as the hoisting works are completed, the construction force will immediately begin the erection of the mill building. Mr. Campbell, being in a hurry to get the stamps working, simply put the machinery in place, erecting no building at the time. Now, however, it will be put up, and will be a very large and complete structure.

San Benito.

PROSPECTING.—*Advance:* Sam E. Moore and David Labiff, Sr., are down from the Chalome mines this week for a short vacation. For the past eight months they have been engaged in running a prospect tunnel for Flint, Birby & Co. The mine is situated about nine miles distant from San Benito and about a mile and a half southeast of the Pinacles. The tunnel has reached a length of 415 feet, the dimensions being 4x6. The tunnel runs through what appears to be a mixture of lime rock and quartz. Continual drilling is necessary and the debris is conveyed to the mouth of the tunnel in wheelbarrows. Crosscutting will begin shortly. The indications for finding pay quartz are very good, and the boys expect to uncover a bonanza before long.

Shasta.

LEASED A MINE.—*Courier:* Jim Salles and Wm. Obvnewel have leased the Spanish mine on the old Wiser place and have been working on the property, with the expectation of developing a bonanza.

Siskiyou.

RICH LAROS.—*Yreka Journal:* The Lewis Bros. and Esslick are meeting with great success in developing their quartz mine in Oro Fino district, Scott valley, about a mile from the town of Oro Fino. They found a prospect of \$10 to the pan on the surface, and find equally good prospects over 30 feet below the surface in their prospecting shaft, with gold plainly visible to the naked eye all through the ledge. The ledge, on account of its richness, was at first supposed to be only a pocket, but the more it is developed the more certain it appears to be a permanent mother lode, varying in width from 33 inches up to 7 feet. The owners feel confident that they have the best quartz mine in Siskiyou county, or on the coast—in fact a bonanza likely to prove a great fortune to them.

Wright & Co., at Oro Fino, have their large ditch full to overflowing with water, and are now busily engaged in operating their giants, to take out a great quantity of dust this year of great value, as Oro Fino dust is considered the richest in the county, as the Spanish name of the place indicates, and so called for that reason when first discovered over 40 years ago.

Manuel Brazil, who owns a placer mining claim at Hawkinsville, took out a nugget last Wednesday which paid \$125. Other claims in the vicinity are also reported as paying well, with a good supply of water from the gulches to permit success in washing pay gravel for a long time this season.

Siskiyou.

CINNABAR SPECIMENS.—A Klamath river correspondent of the Yreka Journal says he has shown some specimens of cinabar from a quicksilver mine owned and operated by P. C. Lange, about four miles below Oak Bar, on the Klamath. The specimens were very fine, nearly 60 per cent of the gross weight being quicksilver. In this mine is also found a character of crystallized mercury which is very rare, and for which Chinese merchants in San Francisco pay from \$2 to \$12 per pound.

Trinity.

A CLEAN-UP.—*Journal,* April 7: A partial clean-up was made last week in the Mammoth mine at Red Hill, the property of Lorenz & Leibbrandt. From the first five boxes of the flume \$7000 was realized. The owners are confident of making a larger clean-up than usual this season.

NEVADA.

Washoe District.

OPERATIONS IN COMSTOCK MINES.—The following additional official news of last week's operations in Comstock mines has been received at the local offices of the companies:

In the Consolidated California and Virginia mine, on the 1650 level, the drift running north from the end of the crosscut ran east from the drift run north from the east crosscut No. 1 from the north drift from the winze—down 52 feet—has been extended during the week 27 feet; total length, 96 feet; continuing in porphyry, clay and quartz of low assay value. Have done some prospecting work in the vicinity of the winze down 20 feet, but no ore has been extracted. 1000 level—The Rule drift—The drift running north, 50 feet above the sill floor, from the upraise which was carried up at a point 353 feet south from the shaft station, has been extended 25 feet; total length, 50 feet; continuing in a clay and porphyry formation. A south drift from the upraise, 50 feet up, has been advanced 15 feet in a porphyry formation. West crosscut No. 4, 527 feet south from the shaft station, has been extended 33 feet; total length, 48 feet, in porphyry with streaks of quartz of only nominal value. From this west crosscut, at a point 15 feet in from its mouth, a north drift has been advanced 20 feet, showing porphyry with streaks of quartz of very low assay value.

In the Ophir mine the north drift near the end of the old Central tunnel, which will soon connect with the old Mexican shaft, was reopened and repaired during the week 54 feet; total length, 196 feet. On the 1465 level the crosscut running west from the drift run north from the crosscut run west from the main north drift on the sill floor of this level, at a point 124

feet south from the winz station, has been extended during the week 10 feet; total length, 70 feet, and stopped in very hard rock. From the crosscut running from the main north drift, at a point 219 feet in from its mouth, a north drift has been advanced six feet in porphyry, showing lines of quartz. Have continued (jointly with the Mexican Company) the work of making repairs to the incline shaft which descends downward from the 1465-level station of the main shaft. In the Mexican mine on the 1465 level the upraise near the mouth of the crosscut run west from the drift run south from the top of the upraise which was carried up 45 feet above the sill floor of this level at a point 40 feet west from the main north drift, and 100 feet north from the south line of this mine, has been carried up during the week seven feet; total height, 58 feet, continuing in a very hard porphyry formation. In the Andes mine, on the 420 level, west crosscut No. 3 was extended 15 feet; total length, 139 feet; face in porphyry.

In the Hale & Norcross mine, on the 900-foot level, they advanced the south drift 13 feet; total length, 170 feet; face in porphyry. 1100 level—Advanced the south drift 12 feet; length, 167 feet; face in porphyry.

Devil's Gate District.

PROSPEROUS MINES.—Territorial *Enterprise*, April 4: "Silver City will send no contingent to join the Industrial Army on its march to Washington," said a resident of that prosperous mining town yesterday. There are no idle men in Devil's Gate district; though all are not making wages, those who are not have a fair prospect of doing so, as they are always at work endeavoring to develop ore streaks that will pay.

Taylor's mill is now running on ore from the Oest mine, and the cleanup will leave a margin of \$15,000 or more in gold bullion.

The Southend location is showing a two foot vein of gold-bearing quartz averaging \$50 per ton, and the vein is widening as depth is attained. This location is owned by F. A. Bierke and is worked on royalty by Harry Brown.

At the Silver King, William Naleigh is finding some fair-grade ore, after several months spent in prospecting.

At the Haywood, Colonel Quinn is taking out considerable pay ore, and several other locations in the district are paying fairly well.

Flowery District.

SIX-MILE CANYON NOTES.—*Virginia Enterprise*, April 6: The mild temperature of the past few days has released the motive power of the mills along Six-mile Canyon creek, and the ore accumulated during the winter months will soon be pulverized. Prospectors have been working in Flowery district through the winter without making any important ore discoveries; but, as they are continually delving in ground that has heretofore produced a large amount of bullion, the prospect of making important ore strikes is favorable. In 1870 a pocket was found in the Golden Prize location in that district from which \$60,000 in gold is said to have been extracted from a space not exceeding six square feet, and it is probable that many more deposits of that kind will eventually be developed.

Benjamin Pfeiffer, the owner of the Lady Bryan, is preparing to develop the surface workings of that property this summer, and, as he has his own mill and team, he will be able to operate the property on a self-sustaining basis.

The veteran prospector and "bard of Six-mile canyon," Andrew Jackson Sheppard, has made several strikes of pay ore in the past ten years, and is hopeful of making a good cleanup in the next two months.

Several owners of blanket claims along the course of Six-mile Canyon creek will turn their attention to placer mining, as the returns from sulphuret concentrations obtained from ore tailings barely pay expenses. Coarse gold has frequently been found in the bed of Six-mile Canyon creek, but not in sufficient quantities to make it remunerative.

The surface workings of locations in Flowery district all show a preponderance of gold in the quartz veins; and, as the low price of silver has made mining for that metal unprofitable, prospectors are devoting their time exclusively to a search for the yellow metal, and Flowery district offers better inducements to gold-seekers than any other locality in this county.

The owners of the Brophy mine in Flowery district, which is patented ground, are wealthy San Franciscans, and they propose to resume the development of that property at an early date. Several gold-bearing quartz ledges have been uncovered in the Brophy, the ore from which could be profitably worked if the company erects a water-power mill on the creek and operates the mine economically.

ARIZONA.

GOOD PROSPECT.—*Globe Silver Belt*: E. J. Edwards and his son, Aaron, returned on Tuesday from a trip to the old mine near Salt river, discovered some months ago, and which is being exploited by Globe parties, C. B. Edwards among the number. Rock carrying gold was discovered, which has since developed into a very good prospect. Mr. Edwards was very favorably impressed with the mine.

A Mexican is reported to have found two gold nuggets in Gold gulch recently, one valued at \$10 and the other \$8.50. There is considerable prospecting for gold going on in that locality.

PROSPECTORS BUSY.—*Phoenix Review*: Speaking of prospecting the other day a well known mining man said: "There are at present within a radius of a hundred miles from this city three times as many prospectors as ever before. Ample spring rains and bountiful snows in the mountains have made it unusually favorable for those searching for gold mines to prosecute their work, and the sturdy miners are taking advantage of the opportunity. The activity so

far has been attended with good results, but many parties have not yet reported. Many claims, however, are being recorded, and confidential friends are daily button-holed and carried to a convenient place to be shown rich specimens."

BRITISH COLUMBIA.

LEDGES OF GOLD ORE FOUND.—A Victoria dispatch, March 31, says: A gold quartz ledge 24 feet wide and assaying \$10 to the ton has been found at Pitt lake, 25 miles from this city. It is considered a peculiarly valuable find on account of its proximity to the transcontinental lines and the large quantity of ore in sight.

The rich strike is said to have been made at China creek, Alberne, by Edward Wilkins. The vein is over 700 feet wide, and there are thousands of tons of rich ore in sight.

OREGON.

A SPARTA MINING PROPERTY.—Baker City *Democrat*: Mr. George Shindler was in the city recently purchasing supplies to be shipped to the Cove mine, in Sparta district, on what is known as Murray gulch, and only about one mile from the Ollie Woodman mine, which has recently come into considerable prominence. The Cove is owned by Messrs. Geo. Shindler, O. S. Buckland and Charles Slade. It was located last year by Messrs. Buckland and Slade, and a few weeks since a third interest was disposed of to Mr. Shindler, who immediately went to work to develop the property. At this time a shaft 50 feet in depth has been sunk, the ledge at this depth being 1½ feet wide, the ore prospecting very rich in gold. The owners are very sanguine of their prospects and will continue development.

SETTLED ITS DEBTS.—*Jacksonville Times*: The Myrtle Creek Mining Co. has settled its debts by paying about 85 cents on the dollar and all costs, and will continue operations on a large scale.

J. A. Martin, of Footh Creek, called on us Friday, from whom we learned that Messrs. Goldworthy, Bailey and other miners in that district have again bonded their placer mines.

The dam at the Simmons-Cameron mine, near Waldo, which went out in January, was soon afterward replaced, and operations are progressing there with a full head of water and good prospects. A late season is expected, on account of the deep snow in the mountains. Swinden & Hayes, who are mining in Josephine county, near the Redlands nursery, feel greatly encouraged, as they have picked up several nice nuggets lately, one of which weighed \$136 and another \$85.

J. Smith and John Miller, who have been prospecting in Gold Hill district, have struck a rich pocket of quartz, from which they have abstracted considerable gold.

WASHINGTON.

THE WENATCHEE PLACERS.—*Cor. Spokane Review*: W. E. Schute came down from his placer claims Saturday, bringing evidence in support of his assertion that a mining excitement is already on in the district. Mr. Schute located his claims two years ago. They lie just below the mouth of the Peshastin on the Wenatchee river. He has found during the past week a clearly defined pay streak, which is rich enough to pay good wages with a pan. He brought with him the product of one pan of the dirt, which weighs 65 cents in coarse gold. Charles Burch, a practical mining man, says there is as much more fine gold in the cleanings that Mr. Schute had not the facilities to save. He panned out \$2 in less than two hours with a rocker. This pay streak is about 18 inches wide and from 18 inches to five feet deep. This discovery explodes the generally accepted belief that placer mining on the Columbia river and its tributaries must be confined to surface operations. Charles Burch, one of the early settlers, says the ground located by Messrs. Schute and Moody has been worked off and on for 20 years, always with more or less success, and the opinion has always prevailed that a rich pay streak existed; but not until now has it even been found. The quartz miners from Peshastin, years ago, depended upon this field for a "groh stake" when returning from fruitless prospecting tours. Fred Patterson has a claim adjoining that of Messrs. Schute and Moody, out of which he took \$270 in a few days' work last fall.

The wagon-road around Rocky Point is nearly completed. This will remove a dangerous obstacle and promote travel to and from Wenatchee and points in the Big Bend and Okanogen country.

The steamer Ellensburgh will make her first trip down the river on April 1st. Captain Hansen will be in charge this season.

Prospectors and miners are daily outfitting for their summer mining operations.

—The following figures give a condensed statement of the operation of the proprietary and leased lines of the Southern Pacific Company for the years 1892 and 1893, ending December 31st of both years:

	1893.	1892.
Gross transportation earnings.....	\$48,049,643 32	\$48,972,195 20
Freightage, rentals and other receipts....	653,609 68	993,705 05
Total receipts.....	\$48,703,253 00	\$49,965,900 25
Operating expenses.....	\$30,576,244 06	\$31,288,199 27
Betterments.....	1,201,833 95	2,301,737 26
Fixed charges and taxes.....	16,135,723 47	15,767,351 89
Total expenses.....	\$47,913,801 48	\$49,357,288 42
Balance.....	\$ 794,366 62	\$ 308,611 84
Income from investments of S. P. Co.....	311,459 63	211,932 66
Balance—Expense in reconstruction of road and additions..	1,106,796 65	620,644 49

Coast Industrial Notes.

—The terra cotta works and Starr mills of Vallejo will soon resume operations.

—It is reported that application has been made for a franchise to build and operate an electric line between Nevada City and Grass Valley. The promoters of the enterprise are Virginia, Nev., capitalists.

—It is learned at San Diego that the National City & Olay Railroad Company has obtained a right of way for the extension of its line from Tia Juana across the Mexican line and up the Tia Juana valley to Hot Springs, a distance of about six miles. The purpose of the extension is to establish the headquarters of the Mexican Land and Colonization Company at Hot Springs instead of at Ensenada, in order to be more accessible to San Diego.

—The Southern Pacific Company will move its headquarters from the corner of Fourth and Townsend streets to the new building of the Union Trust Company, corner of Market and Montgomery streets, on the 1st of next November. Arrangements for carrying out this object were completed last week and a lease for ten years, subject to renewal on favorable terms, was signed by H. E. Huntington, representing the Southern Pacific, and I. W. Hellman, who acted for the Union Trust Company. The provisions of the lease have not been made public, but it is known that the annual rental is \$20,000. The building consists of seven floors. The first will be devoted to the business of the Trust Company and the six above that point will be occupied by the railroad company's offices.

—Further complications have arisen between the Bear Valley Company and the people of the Moreno and Alessandro Company. The Board of Directors of the Alessandro Irrigation district has rescinded the action taken a fortnight ago by which they proposed to pay interest on the irrigation bonds which the Bear Valley people held, provided the latter would pay into the treasury of the irrigation district some \$25,000 due as taxes. Foster, who represents the English stockholders, yesterday made a formal demand on the treasurer of the district for \$16,000 due on coupons of the district's bonds. The demand was refused. The people of the district say that they should not be compelled to pay interest on their \$750,000 of bonds until Bear Valley places water on their lands according to contract, the bonds having been assigned to that company on condition that it provide the water.

—The latest census bulletin gives the following figures for the year of 1890: True value of real and personal property in California, \$2,533,000,000; Washington, \$760,000,000; Oregon, \$590,000,000; Nevada, \$180,000,000; Arizona, \$188,000,000; New Mexico, \$231,000,000; Utah, \$349,000,000. New York leads with \$8,560,000,000. Wyoming is the poorest of the States, with \$169,000,000. The per capita of valuation for the entire country has increased from \$308 in 1850 to \$1039 in 1890. The per capita in California has increased from \$239 in 1850 to \$2097 in 1890. California had in 1890 52,894 farms, including lands both improved and unimproved, over 21,000,000 acres. California stood sixteenth in the number of horses owned, as well as in mules and asses. She stood twenty-sixth in the number of work oxen, seventeenth in milch cows, seventh in other cattle, twenty-second in swine, third in the number of sheep, including spring lambs, and second in pounds of wool produced in 1890. Ohio headed the list with nearly 21,000,000 pounds, California shearing over 16,000,000. California headed the list of barley producers with 17,500,000 bushels. She was second in wheat, with 40,000,000 bushels, Minnesota leading with 52,000,000. California was third in hops, with 6,500,000 pounds, Washington producing 8,000,000 and New York 20,000,000. California was second in bean raising, having 700,000 bushels, against New York with 1,100,000.

—A bulletin issued by the Census Bureau gives the statistics of the various manufactures in the several States, including sixty-seven different lines: California is shown to stand as to the value of products in the different branches as follows: Agricultural implements, ninth; blacksmithing and wheelwrighting, seventh; boots and shoes, tenth; bread and other bakery products, eighth; brick and tiles, eleventh; carpentering, thirteenth; carriages and wagons, fourteenth; cars and general shop construction and repairs by steam railroad companies, eighth; dairy products of factories, nineteenth; chemicals, tenth; men's clothing, custom and repairing, sixth; same, factory product, tenth; woman's clothing and dressmaking, sixth; woman's clothing, factory product, sixth; coffee and spice roasting and grinding, sev-

enth; confectionery, ninth; cooperage, eleventh; fertilizers, sixteenth; flouring and grist mill products, eleventh; foundry and machine shop products, twelfth; furniture, twelfth; illuminating and heating gas, fourth; hats and caps, other than wool, ninth; iron and steel work, seventeenth; architectural iron work, tenth; jewelry, seventh; leather, tanned and curried, sixth; distilled liquors, fourteenth; malt liquors, eleventh; lumber mill products, fourth; planing mill products, tenth; marble and stone work, eleventh; masonry, brick and stone work, eighth; millinery, eighth; painting and paper-hanging, tenth; paints, ninth; paper, fifteenth; patent medicines, thirteenth; paving and paving materials, fifth; plumbing and gas-fitting, twelfth; book and job printing and publishing, eighth; newspaper and periodical printing and publishing, seventh; saddlery and harness, eleventh; shipbuilding, fourth; shirts, fifth; silk, seventh; wholesale meat slaughtering and packing, seventeenth; soap and candles, eighth; sugar and molasses refining, second; chewing and smoking tobacco, fifteenth; cigars and cigarettes, ninth; woolen goods, fourteenth.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 60-horsepower engine and 45-horsepower boiler, with ore-crusher and other machinery. Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care Mining and Scientific Press, San Francisco.

THE GOLD AND SILVER EXTRACTION COMPANY, OF AMERICA.

LIMITED.

TRADE MARK.

MacArthur-Forrest Cyanide Process.

CAPITAL, £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto unextractable at a profit, the MACARTHUR-FORREST CYANIDE (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.

Advisory Board in the United States: Thomas W. Goad, Mgr.; Hugh Butler, Att'y; John F. Bell, P. G. George Gow.

OFFICE:

McPHEE Building, DENVER, COLORADO. Agency and Experimental Plant, Mechanical Arts Building, Midwinter Fair, San Francisco, Cal.

PIONEER REDUCTION CO.,

NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ore or concentrates.

Address all communications to

PIONEER REDUCTION COMPANY, NEVADA CITY, CALIF.

ALEX KELLER, MINERALOGIST,

704 Powell St., San Francisco, Cal.

A large variety of Mineral Specimens, large size or small to suit. See collection, three cases, in Placer County Mineral Exhibit at the Fair. Also all kinds of mineral resource and capital wanted to help develop them. First class chances to invest. Postal or note to the above address will find a ready response.

PORTLAND MINING BUREAU.

Mining Properties in OREGON, WASHINGTON and IDAHO Listed For Sale.

ORES EXHIBITED AND ASSAYS MADE.

W. C. COWGILL, Secretary.

Room 9, Chamber of Commerce Building, PORTLAND, OR. P. O. Box 359.

J. F. CROSETT, Commission Mining Agency.

628 Sacramento St., San Francisco, Cal. Buy and Sell Meritorious Mining Properties. I have orders for Income-Paying Mines at the present time. Have also some good properties for sale. I want more mines to offer to purchasers and also desire more purchasers to examine properties I have to offer. Correspondence solicited.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Market Reports.

The Markets.

SAN FRANCISCO, April 12, 1894.

After appearing to have recovered its legs last week, silver weakened and receded. It is now, however, in somewhat better condition than it had recently been.

The London Statist, in sketching the history of the silver market since 1888, concludes that the recent fall in the price of silver was due to panic, and that its recovery is inevitable if the Indian mints are reopened, perhaps to 36. But the Statist adds that the extent of this depends on whether India will resume buying on the usual scale.

New York Prices.

Mining Share Market.

SAN FRANCISCO, April 12, 1894.

The Comstock market during the week has had in the main a strong tone. It has been the most active and profitable week the brokers in Comstock shares have had for a month past. There were lively fluctuations in the leading stocks, and a large trade was done in the smaller-priced ones.

The interest among brokers and dealers centered chiefly in Ophir, but Potosi to the middle group had strong backing, and some of the Gold Hill shares were in good demand. Ophir stock was evidently under the control of inside operators, for brokers who are known to represent them had a great deal to do with its ups and downs. At the opening yesterday Ophir rose to \$3.20-3.25, and afterward had a further advance to \$3.40, which is the highest price the stock has reached since last December, in which month Con. California sold at \$5, and the whole line of Comstock shares was booming over the so-called Rule project, which resulted so unsatisfactorily. Later in the forenoon Mr. M. Ser supplied the market with Ophir, and the price went back to \$3.05, but it was evident at all times that some skillful manipulation was in progress.

NOTES.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order. American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

HYDRAULIC AIR COMPRESSOR.—Emile Schultz and John H. Henderson, Sierra City, Cal. No. 517,628. Dated April 3, 1894. This invention relates to an apparatus for injecting and compressing a body of air by the application of a column of water under pressure. The object is to inject into compressing cylinders, by means of jets of water under pressure, a body of air larger than can be supplied by simple displacement, and at the same time to cool this body of air by contact with the water and to compress and deliver it into transmitting pipes and receivers. The mechanism by which this is effected consists of vertical cylinders having inlet pipes with oppositely moving controlling valves near the opposite ends of the cylinders, and mechanism for operating the valves, so that water is alternately admitted under pressure into the cylinders and discharged therefrom, and a jet nozzle and air inlet valves through which the air is drawn and injected with the water into the cylinders, and certain other details of construction which cannot well be explained without engravings.

A DISCHARGE ATTACHMENT FOR OIL CANS.—William Mathews, Alameda, Cal. No. 517,618. Dated April 3, 1894. This invention relates to a device whereby the contents of liquid containing cans may be drawn therefrom and leakage and dripping from the discharge nozzle avoided. It consists of a chamber having a hole in the top and a can having an extension in its top, with a spring-actuated closing valve opening inwardly. This can being inverted so as to stand upon the chamber, first referred to, the valve will be opened to allow the liquid to flow into the lower chamber, in which it rises to the edge of the can extension which projects into the chamber and is there arrested, because no more water can enter. The draw-off pipe consists of a tube connected with the bottom of this chamber, this bottom being flexible so as to allow the pipe to be depressed or raised. When this pipe is in its normal position it is held up by a spring, and the discharge end, making a reverse curve, is above the level of the liquid in the chamber. When it is depressed, the liquid will flow out as long as it remains in this depressed position, but when the tube is released it will rise to its normal position and stop the flow.

CONTINUOUS KILN.—Peter L. Youngren, Oakland, Cal. No. 517,637. Dated April 3, 1894. The objects of this kiln are, first, to provide means for water-smoking all parts of the kiln equally; second, to provide for regulating the degrees of heat and velocity of circulation in the water-smoking section of the kiln; third, to obtain a more uniform degree of heat in the burning section; fourth, to provide means for controlling the passage of air through and above the burnt brick; and fifth, to provide that certain parts of the operation shall be automatic. These several objects are attained by means of the peculiar construction and arrangement of the parts of the kiln, the principal features of which are a rib or barrier in the crown of the kiln, provided with suitable damper-controlled openings, said openings being, preferably, automatically controlled by means of supporting the dampers upon the settling ware and transverse flues extending under the compartment floors and connected with a supplementary furnace.

ROTATING GRAIN METER.—John M. Finch, Marysville, Cal., assignor of one-half to Frank Miller of the same place. No. 517,608. Dated April 3, 1894. This meter is an improvement in that class of weighing apparatus in which a rotary wheel, having upon its periphery suitable receptacles for the material to be weighed, has connected with it a check or balance adapted to retard its movement sufficiently and pro-

Assessment Notices.

SUPERIOR MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Placerville, El Dorado County, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 13th day of March, 1894, an assessment (No. 1) of Twenty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the delinquent at the office of the company, Room 17, 315 Pine street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 14th day of May, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors.

R. W. HEATH, Secretary.

Office, 318 Pine St., Room 17, San Francisco, California.

Universal Brass Worker.

Mechanical ingenuity keeps pace with advancing requirements. The illustration on this page is of a Universal brass worker, made by the Lodge & Shipley Machine Tool Co. of Cincinnati, O., which is of practical interest to all machinists.

Its main advantages are: After the machine is oiled and started in the morning it need never be stopped for the purpose of putting in or taking out work. The spindles are so arranged as to perform the five operations necessary to a valve body, viz.: boring, facing and threading of the two ends, and boring, facing, turning and trimming body seat, and threading of same, and the final seating of the valve. It may also be used on stuffing-box nuts, making two at a time, and performing all the operations. It also may be used on bonnets and stems. The machine is very powerfully geared. While boring spindles run 600 revolutions, the tapping spindles run only 150; thus giving slow speed and great power, at the same time preserving the edge and the temper of the taps used.

Universal chucks are fitted to each spindle, which center the tools perfectly. In addition to this the inner ends of spindles are fitted with milled slots to receive flatted end of shank, which makes a positive drive for same in addition to the grip of the chucks. The revolving chucks are fitted on a revolving table, and this table is indexed into six divisions. The extra chuck is used for putting in rough and taking out finished work. Each of these revolving chucks is indexed and all come in absolute alignment with each of the five spindles. The index lock key for the revolving table is operated by a treadle near the base of the machine, while the lock key for each of the revolving chucks, which are carried with the revolving table, is lifted by the knee of the operator while the chucks are being revolved. The boring spindles are geared three to one, and the tapping spindles nine to one. A central upright shaft fitted with two gears drives both boring and tapping spindles.

The tapping spindles when not in use revolve in an opposite direction to that assumed when tapping. The moment the tap touches the work it reverses and moves forward, and when at the proper depth releases automatically and returns to its former position. Power is taken from a horizontal shaft, having a three-step cone and a four-inch belt, and is engaged by means of a steel bevel pinion into one of a larger diameter.

UNDETERRED by the result of the Brussels gathering, the Mexican Government is asking that an international monetary conference be held at the City of Mexico to attempt an adjustment of "the silver question."

SILVER and wheat are always affected simultaneously. When one goes up or down, the other does likewise. They both rose together a little during the past week.

From the Okanogan Country.

Judge Ferdinand P. Wehe, one of the famous four Wehe brothers, who have done so much for the development of the mining interests of the Northwest, is in the city. He reports mining matters at Loomiston, Wash., his home, encouraging. In that vicinity are the Black Bear, Tribune, Spokane and War Eagle, each with a well-

THE UNIVERSAL BRASS WORKER.

defined ledge of free-milling ore, and the Mayflower, Sherman and Sacramento group showing smelting ores, all being rich in both gold and silver. Judge Wehe is now awaiting the arrival of ore to place on exhibition at the Midwinter Fair; and, like all Washingtonians, is enthusiastic over the future of his adopted State.

THIS time it is Prof. Falb of Vienna who comes to the front telling when the world will end. He says a comet will smash us November 13, 1899, and that will end the world. All right; we'll get along just as well without it.

The Electrolytic Process.

The times are prolific of new ways and means for the extraction of gold simply and economically, and from London come accounts of an electrolytic process which, it is claimed, is capable of satisfactorily extracting the gold from all classes of gold ore, including the most refractory. Electro-chemical processes are no novelty, and a great

deal of effort has been expended in demonstrating their value. As in other modes of extraction, it has been found that different processes are best adapted for different kinds of ore, and such experiments are necessarily very costly, and when the character of the ore changes it upsets the plans of the reducer. The process so well commended in London seeks to secure the circulation of the pulverized ore between positive and negative poles by setting a screw propeller vertically near the bottom of the tank. For a solvent is used a dilute solution of potassium cyanide. The electrolyzed gold is collected by a bath of mercury constituting the negative pole, and the positive pole—the fourth quantity in the equation—is a mass of powdered rosin. Mixed with water the ore in the tank comes in contact with the mercury bath at the bottom. The revolving screw starts the mixture circulating down the center of the tank, touching the surface of the mercury, again traveling up the conical sides of the tank on which is laid the positive pole and so down again in the center, where it is forced into the mercury, thus, it is claimed, causing every particle of gold to be absorbed and electrolyzed, so that ninety per cent of the gold is secured. The inventors of the process say that the ore needs only to be crushed before being placed in the tank; that whether free-milling or rebellious ore the treatment works equally well; that there is little or no waste, the same chemicals admitting of repeated use and that one operation will suffice for the entire contents of the tank.

So much is claimed for this process in the important elements of efficiency, simplicity and cheapness, that it will attract considerable attention among mining men the world over, and if it stands the practical test of merit will come into general use.

THE *Amador Record* is a good illustration of what a clever newspaper can do in judicious and enterprising presentation of facts and figures showing the advantages of the locality from whence it derives its support. It has recently issued a mammoth illustrated edition, comprising a complete write-up of the county, that would be commendable to any newspaper anywhere, and which is a splendid showing for *Amador* and the *Record*. Every industry in the vicinity and every work of any magnitude is faithfully and intelligently portrayed, and great credit is due the paper that made such an undertaking possible.

UNDER the present tariff there is about \$2.50 worth of wool in a fine suit of clothes.

Idle Men and Idle Money.

One morning this week the city dailies had two items—one, that the San Francisco banks had \$15,000,000 deposited that they could not use nor lend; the other, that the second division of the "California Industrials," the army of the unemployed, 500 strong, were to start for the East, via Mojave, the city providing for their transportation.

The simultaneous announcements is a sad commentary upon the condition of the times. Plenty of money, the bank vaults bursting with coin, and idle men leaving the State—assisted emigrants. The men were out of work; the money is "out of work" too.

There is just as much money as ever—more in the banks than ever before. There is just as many deserving men looking for work—more than ever before—but there is a universal lack of confidence. The country needs a big dose of faith cure. Everybody has grown afraid that if a dollar is let go it will never again be seen, and the result is tersely exemplified in the fact of a paralysis of investment and a plethora of coin; men and money both idle.

A Call for Aid.

To the Miners of California and those Interested in the Success of the Mineral Industry of the State:

GENTLEMEN: The committee having in charge the mining exhibit of the California Midwinter International Exposition have labored ardently to try to raise money enough to carry on the exhibit to July 1, 1894, but find that they are short the amount of \$225,568.

San Francisco has been more than generous in the support of our mineral exhibit. She has had many calls upon her in aiding different interests at the Midwinter Fair, also in assisting the unemployed through the last winter, and we cannot at the present time raise any more money here, so we are compelled to call upon the miners of California, and the merchants and those interested in the welfare of the mineral industry, to assist us as far as they possibly can toward carrying on the mineral exhibit to July 1, 1894.

Yours, respectfully,

By W. C. RALSTON, Secretary. EXECUTIVE COMMITTEE.

SAYS the Downieville Mountain Messenger of the 14th:

George Ohleyer is again pressing himself to the front in defense of the anti-debris cranks, and his wise (?) sayings fill almost one entire column of last Friday's Appeal. Ohleyer's object is so plain that it has long been a wonder to us that the farmers who are "putting up the stuff" don't drop on him. It is big money in his pocket if he and others of his kind can only keep up the row between the farmers and miners; and, whenever he thinks things are cooling down a bit, he proceeds to stir them up again. If it were not for this class of vampires sucking the valley people's blood and emptying their purses, the differences would have been patched up long ago and everything now be serene. The valley folks will drop on him and his schemes before long, we hope.

WITH a partial understanding of the subject, the London financial journals say that the future of silver depends upon the reopening of the India mints,

Recent Work of the Commission.

The California Debris Commission has issued permits to work to the miners or operators of the Eureka hydraulic, the Spanish Hill gravel and the Spanish Hill hydraulic mines, in the vicinity of Placerville, and to the Grub Flat mine, near Meadow Valley. A temporary permit for the present season only has been given the Quincy Water and Mining Company, using a log dam to restrain the debris. Meanwhile the company proposes to build a stone dam in Spanish creek for permanent restraining use.

The application of the Badger Hill mine, near Spanish Ranch, has been held in abeyance till the Quincy Company's dam is built. The cost of the dam will be shared by both companies.

Authorization has been issued to the Kate Hayes Company to put restraining work in the Manzanita mine, near San Juan, utilizing an old hydraulic pit therefor as a settling reservoir. There is an old tunnel under the pit, to which a shaft will be sunk, and through which the surface water will run, similar in substance to the company's works at the French Corral mine.

Lient. Gillette has returned from a visit to the Excelsior mine at Smartsville. While there he sampled the water coming in from the ditch, and also flowing out from below the impounding dam. The ditch water carries sediment; the outflow having considerably less than the inflow. The old channel at Timbuctoo is now used for a discharge for the Excelsior's tailings, being a sort of settling reservoir.

The Excelsior's operations are at present more extensive than those of any other mine running under the requirements of the Commission. It is using upwards of 1500 inches of water, and, during March, washed 60,000 cubic yards of material, chiefly gravel.

Silver Industry of Chili.

A report prepared by direction of the Sociedad Nacional de Minería (the National Mining Society) on the silver industry of Chili was recently presented to the Government of that country. A synopsis of this report has been received by the Bureau of the American Republics in Washington, D. C. At the date of the report the production is estimated thus:

	Marks.
The silver exported from Iquique, Taltal, Caldetia, Coquimbo and Carrizal reaches and exceeds.....	300,000
The silver extracted in the Bella Vista Works, Antofagasta, from ore from Chilean mines exceeds.....	180,000
The Las Condes, San Jose de Maipo and other fields yield upward of.....	100,000
Total.....	580,000

To this quantity the compilers of the report add:

From Huanchaca.....	350,000
From Oruro.....	222,000
Total.....	1,152,000

Although neither Huanchaca nor Oruro are Chilean fields, the latter belong exclusively to Chileans, while of the 320,000 shares of the former 101,000 are held by Chileans, and of the "acclones al portador" (share of stock payable to bearer) four per cent is held by Chileans. Therefore, the compilers of the report consider that 35 per cent of the production of Huanchaca, calculated in round numbers at one million marks, belongs to Chileans. The grand total of 1,152,000 marks is equal to 264,960 kilograms of silver. Taking the production at 1,100,000 marks, and the price at £1 13s per mark, we have a total of £1,243,000, which at 15d, the rate of exchange at the date of the report, is equal to \$19,888,000.

From the facts given in the report it would appear that the prospect for remunerative working of the Chilean silver mines is not encouraging, with the exception of a few exceedingly rich mines. Commenting upon this feature of the report the *Chilian Times* says: "The consequence of such a state of affairs as that depicted by the report is not very agreeable to contemplate. The paralyzation of the silver industry would mean the withdrawal of \$20,000,000 of 15d from the annual exports. It would mean the cessation of trade with Bolivia, the loss of a chief source of revenue to the steamship companies, and the partial ruin of agriculture. In order to prevent a catastrophe of this nature the compilers of the report propose a double standard, without any legal ratio between the two metals. And they go on to say: The solution would be obtained in an agreement to coin in all America a money to be current in all the States, of a fixed weight and standard, to be coined by the Government only. The proportion to be coined by each Government might be fixed by agreement, but silver-producing countries would probably prefer not to be bound by a stipulation of this kind. It will be seen from these extracts that the compilers of the report favor bimetalism, and in another part they advocate free coinage of both metals."

Digest of Recent Court Decisions.

Exception of Mines and Mining from Town-Site Patent.

In order to except mineral lands from the operation of a town-site patent, they must be known to be valuable for mining purposes at the date when the patent takes effect; and it is not sufficient that they have once been valuable for mining purposes, or are afterward discovered to be still valuable therefor. When a quartz ledge, known to be gold-bearing and to have been profitably worked prior to the acquisitions of a town-site patent in the year 1866, and not then worked out, is situated within the exterior boundaries of the patent "the rights of the Government and its mining grantees are not limited to such actual mining or tunnel possession as may have existed before the town-site patent, or to any continuance of a mining claim or possession by prior locators or their grantees, but the Government owns and can grant the right to any quartz mine or gold-bearing ledge which was known to exist and to be valuable for minerals before the town-site patent was obtained, and which was not worked out when the town-site patent was obtained; and the rights of a subsequent locator under the Government by virtue of its reservation of the mine, and of the mining acts of 1866 and 1872, include a reasonable quantity of surface for the convenient working of the ledge, not exceeding three hundred feet on each side thereof."—*Dower vs. Richards* (Supreme Court of the United States), 14 Su. Ct. Rep. 452.

Construction of Deeds for Mineral Rights.

A deed which conveys "the following tract of land, situate," etc., "that is, the one-half of the mineral interest in the said land" (described by notes and bonds) to have and to hold "the one-half of the mines and minerals" therein, must be held to convey the grantor's entire mineral interest, even if considered upon its face alone; but especially so in the light of the facts, known to both parties, that the grantees had already purchased the fee of the lands for the purpose of making a sale to a company having sufficient capital to develop its mineral deposits, that the sale had fallen through because of the grantor's claim to an interest in the mineral rights, and that the grantees desired to purchase the same in order to perfect and make salable their title. The words in a deed cannot, as a general rule, be added to, explained or contradicted by extrinsic evidence, but where any part is indefinite or ambiguous, or cannot be fully understood as to the intention of the instrument, it may be construed in the light of surrounding circumstances, in which may be considered the position and relation of the respective parties, the objects of the conveyance and the subject matter at and subsequent to the transaction. A court may avail itself of the same light which the parties possessed at the time the deed was executed, and may consider previous and contemporary transactions and facts to ascertain the subject matter, and the sense in which the respective parties may have employed and understood the particular expressions in the deed.—*Brown vs. Cranberry Iron & Coal Co.* (Circuit Court, W. D. North Carolina), 59 Fed. Rep. 434.

Assumption of Risk by Employee.

While several cars in a mine were being propelled to the shaft one of them ran through a switch, left open by mistake, onto a side track, killing an employee. The switch was left open by a gang of night men, and it was the duty of the employee to see that it was properly adjusted for the work of the day. His failure to have the switch in proper condition caused his death. He was an experienced miner; had been employed in the mine for a year and a half and was familiar with the switch and the place where he worked; knew that the night men often left the switch open, and that loaded cars were frequently shoved to the shaft, as this one was, without being attached to other cars or to the cable; and he neither made any complaint nor asked any charges. By so doing he assumed the risks incident in such condition of things.—*Backman vs. Consolidated Coal Co.* (Supreme Court of Iowa), 57 N. W. Rep. 839.

Location and Acquisition of Placer Mining Claim.

It is not necessary that a separate discovery, separate marking of boundaries, separate recording and separate work should be made and performed on each of the 20 acres contained in a 160-acre placer claim, authorized by Revised Statute U. S., to be located under one location by an association of persons.—*McDonald vs. Montana Wood Co.* (Supreme Court of Montana), 35 Rep. 668.

Mines and Mining Liens.

When the statutes as amended by laws 1889, giving to persons who do work on mining property operated by lessees a lien for their labor, unless the owner files for record, "before the commencement of work under the lease," a notice that the property is being worked under a lease does not apply where the lease was executed and the work performed before the passage of the act.—*Gardner vs. Resumption Mining and Smelting Co.* (Court of Appeals of Colorado), 35 Pac. Rep. 674.

Liability of Corporation for Acts of General Manager.

The general manager of a mining and reduction company employed men to open a mine of his own, and to construct a wagon road and ore chute from such mine to the company's reduction mill, transferred miners and tools from the company's mine to his own; reduced his ore at the company's mill, and sold it mixed with ore from the company's mine. As he acted within the scope of his employment, though without the knowledge and in fraud of the company, the company was liable for the wages of the men who were employed by him in the name of the company, and who believed that they were serving the company when working for him.—*Orn Mining and Milling Co. vs. Kaiser* (Court of Appeals of Colorado), 35 Pac. Rep. 677.

FOUR exploring parties are fitting out for the North Pole this spring, and there is the usual supplementary stir among those who will naturally constitute the "relief expedition" and the tertiary formation known as the "second relief expedition" to look for the members of the first relief expedition.

General Mining Notes.

The Gem mine (Idaho) has resumed, giving employment to 150 men.

The Goler mines, in Kern county, have recently imported thirty dry washers, made in Porterville.

The California Debris Commissioners have appointed W. B. Story, of Nevada City, assistant engineer for the Commission.

At a meeting of stockholders of the Idaho Mining Company on the 12th inst., the company as a corporation was voted out of existence.

The world's gold production for 1892 was \$138,861,000. The U. S. Mint Bureau estimates the gold production of the world for 1893 to be \$150,000,000.

In the Ashland, Or., mine a true fissure vein has been found at a depth of 575 feet, and the mining industries of that section are experiencing a "boom."

The Union Pacific Railroad Company has decided that on and after May 12, 1894, the minimum weight on ore carloads will be 20,000 pounds instead of 16,000 pounds as heretofore.

The managers of the mining exhibit at the Midwinter Fair are going to give a purse for a single and double-handed drilling contest, free for all. The purse will be about \$400, the first prize to be \$100.

The South Keystone Consolidated Mining Company has incorporated with a capital of \$200,000, of which \$20,000 has been subscribed. Directors—J. A. McIntire, John C. Hughes, H. K. Hall, William Roush and L. T. Hatfield.

The Mountain Lion Mining and Milling Company of Missouri Flat has incorporated with A. M. Brown, J. W. Farquhar and Geo. H. Rivers as directors. The capital stock is \$10,000, and headquarters are at Grant's Pass, Or.

The Idaho Statesman says a sale has been concluded of Ben Wilson's mining property—placer ground, ditches, machinery, etc.—on Grimes creek, Idaho, for between \$250,000 and \$300,000, to J. C. Kemp Van Ee, the latter representing a strong London syndicate.

The Surprise Gold Mill and Mining Company was incorporated last Monday in San Francisco. Directors—F. K. L. Bonte, F. R. Lemky, Louis Andet, C. C. Cotton and John Gillison. Capital stock, \$1,000,000, of which \$100,000 has been subscribed.

The first steamer load of ore from the LeRoi mine, in Trail creek district, Washington, was taken down the river from the Trail landing to Northport last week. There were 987 tons at the landing, as the result of the winter's work, the steamer taking away 64 tons.

At the recent annual meeting of the Montana Elkhorn Mining Company in London, the chairman in a speech explanatory of the report said that the company was prepared to keep its mines in operation, and expected to make a profit as long as the price of silver did not fall below 20d per ounce.

A DEMINO, NEW MEXICO, dispatch says: Jack Redding and David Harper, owners of the celebrated Dos Cabezas mine in old Mexico, became involved in a quarrel and shot and killed each other. These make five deaths of the owners of this property, which seems to carry with it a strange fatality. Only one owner survives. Five others have met violent deaths.

The Chassell Gold Mining Company has been incorporated by George Peace, John H. Rule, Louis Sponheim and Osmund A. Sponheim of Basin, and George Robertson of Butte, Montana. The company is organized to do general mining business, and the capital stock is fixed at \$500,000, divided into half a million shares having a par value of \$1 each. The stock is non-assessable.

JAOOME, the largest mining camp in Arizona, was entirely destroyed by fire last Tuesday morning. All the business houses are gone, including the records and other property of the postoffice. The fire could not be controlled owing to the heavy wind that prevailed. The loss is estimated at \$50,000, with very little insurance. Many miners and their families are without homes.

TWENTY years ago a seat in the San Francisco Stock and Exchange Board was easily worth \$25,000. That was in the boomy days of the Bonanza mines. The late Martin Bacon left among his assets a seat in the Board, and his widow, May E. Bacon, has been given permission to sell it with other personal property at private sale. It is part of the estate of her children and is appraised at \$1000.

The annual meeting of the stockholders of the Yuba River Mining Company was held on the 10th, the following board of directors being elected: D. E. Matteson and James Vineyard of Nevada county, and E. J. Crowley and Nelson Wilcoxon of Sacramento. The board organized by electing D. E. Matteson president; Jas. Vineyard, vice-president; J. M. Wiley, secretary. Nelson Wilcoxon will be superintendent.

STEPHEN MOORE, superintendent of the Home mine, down Deer creek, says the Nevada City Herald, exhibits a couple of pieces of quartz which came out of the Home years ago, when the old company was working the mine. The pure gold sticks out all through it, and the pieces, no larger than a man's fist, contain probably \$40 worth of gold each. Mr. Moore hopes that he will soon run into about an acre of that stuff.

RECENTLY while the men in the employ of Jackson & McCue, near Folsom, were at work running a drift in the mine, they tapped an old shaft and drift which was filled with water. The minute their picks struck through, a flood of water rushed in, sweeping them through the tunnel to the pump shaft, where they climbed the iron pipes and escaped. The steam pumps have been busy ever since reducing the water, and have the mine dry again.

THAT the Daisy Hill mine will soon be working, the Grass Valley Union says, is a certainty. Recently the first installment of \$5000 was paid by the company organized for working the mine, of which C. L. Kingsley is one of the heaviest stockholders. The Daisy Hill is situated some 200 or 300 yards west of the Oshorne Hill mine. In the early days it was fabulously rich, the ore averaging from \$20 to \$75 a ton, while considerable rich specimen ore valued at \$600 per ton was extracted. The mine was sunk to a superficial depth of 260 feet. Like all

other mines on the famous Osborns Hill it will probably increase in value as depth is attained. George Mainhart, M. C. Taylor and Chas. H. Taylor were instrumental in the formation of the company to work the Daisy Hill.

THERE has been exaggerated reports concerning the magnitude of the Cripple Creek strike. The Mining Record says it affected the pockets of the few rather than of the many. Undoubtedly the owners of the few mines closed down are nearly as willing for them to remain so until the railroads reach there, as the striking miners are to prevent their fellow-men from working at living wages. Two-thirds of the real laboring men of that camp are at work and assisting in keeping up its developments.

THE following from the Jacksonville, Or., Times expresses the sentiments of all concerned: "The special act for the suspension of assessment work on mining claims, passed by Congress last August, should be continued for 1894. The times seem to be harder than ever in most mining sections, especially where silver is the principal product. Thousands of men who have been thrown out of work are industriously prospecting for gold mines, without much means at their command for prosecuting the work, and should be given all the encouragement possible."

THE famous Cripple Creek has a rival in the new camp of Balfour, Colorado. Although the town is only about three months old, it now has about 175 houses and is staked for a radius of five miles in every direction. Cripple Creek people who have visited the field say the indications all point to the same results as in the older camp, the belt being the same and the rock formation also. The only difference is that in Balfour all the shafts strike water. The first shipment of machinery to this camp was made about two weeks ago, and crowds of prospectors are flocking to the new field.

A RECENT LETTER from the Commissioner of the General Land Office says: Mining lands were excluded from the grant to the Oregon and California R. R. Co. so that the discovery of the mineral character of a tract within the limits of said grant, at any time prior to the issuance of patent, serves to except such tract from the operation of the grant. On corroborated allegation that certain land patented to the company is excepted from the grant by reason of the known mineral character, a hearing may be ordered to ascertain whether the facts justify judicial proceedings for the recovery of title.

ARTICLES for the following domestic corporations have been filed with the Washington Secretary of State: Spectacle Lake Gold Mining Company, Loomis, Okanogan county, Washington. Capital, \$1,000,000; 1,000,000 shares of \$1 each. Incorporators—George W. Adrian, Walter M. Adrian and William Foulke; to carry on business of mining. Eureka Placer Mining Company, Leavenworth, Okanogan county, Washington. Capital, \$24,000; 240 shares of \$100 each. Incorporators—John Bjork, Matthias Donehoe, S. Sivertson, L. Y. English, O. Y. Bjork, Frank Lewis; to buy, sell and operate placer mines.

IN the Cour d'Alene district the Poorman mine has resumed work with 250 men. The Bunker Hill mine now has 365 men employed every day. The Gem mine was opened up a week ago and is now working 100 men. The Standard mine is carrying 70 men. The Tiger mine has increased its force from 30 to 74 men. Even the Last Chance mine is expected to resume operations soon, as everybody believes the recent decision of a parallel Montana case will soon give the property to its Spokane owners. All over the Cour d'Alenes people are taking new courage, money is growing more plentiful and conditions in general are growing better every day.

A MOVE is reported at Mont Idaho to work a portion of the bed of Salmon river for gold. Near that point the river makes a large bend, and the plan is to straighten the river at that point by running the water through a large tunnel and then working the bed of the big semicircle. It is believed there are rich deposits of gold all along the bed of the river and the promoters of the tunnel scheme are confident a fortune awaits them if their efforts to change the course of the stream prove successful. The tunnel would have to be about a quarter of a mile long. With the water thus diverted there would be about three miles of the channel that could be operated now.

TWO Vanderbilt mining men, H. Randolph and H. M. Stevens, went to South America last fall to inspect the mines from which such rich reports are made. This week, says Bulletin, after a five months' stay, the two gentlemen returned. They went 1200 miles into the interior of Colombia, passing into Venezuela, crossing the equator. Their report is entirely unsatisfactory, as they saw nothing which would indicate great bonanzas. The richest mine they saw has been worked over 200 years, and has never produced a million dollars. Some small propositions were fair, but not any better than can be found in dozens of camps in the United States. The facilities for working them are as bad as could be represented, and their advice is for the United States miner to stick to home.

CORRESPONDENCE of the Victoria Colonist from Fort Sheppard, B. C., says: "American mining men in this country complain bitterly of what they describe as the petty and unfair interpretation placed by the Dominion custom authorities upon the clause of the act providing for the free admission into Canada of 'mining machinery which is, at the time of its importation, of a class or kind not manufactured in Canada.' They claim that in spite of this provision, no such mining machinery can come in duty free. They instance the special patent steel piping required for hydraulic working, carefully riveted and fixed to withstand great pressure, which is refused admission on the ground that piping 'somewhat similar' is made in Canada, or that some portions of it, such as the rivets, are so made. These gentlemen appear inclined to assume that this is intended as a special discrimination against them and their manufacturers, forgetting that they are not the only users of such machinery in British Columbia nor the sole manufacturers in the world. The numerous Canadian companies operating by hydraulic works here and the heavy imports of mining machinery from the mother country are subjected to precisely the same treatment, without favor or affection. But it would seem that there is some ground for the complaint, and it is believed that all the customs officers in British Columbia are in favor of a more liberal interpretation. At present duties are levied upon all machinery coming in, and the question of a refund has to be thrashed out with the Ottawa office, causing delay and irritation.

General News Notes.

SMALLPOX is epidemic in Chicago, and there are many daily deaths.

THE failure of Mark Twain as a New York book-publisher is announced.

MOORELL, Chris Evans' assistant, has been sent to the Folsom State prison for life.

A \$300,000 FIRE totally destroyed the Sacramento electric power plant last Wednesday.

ALL the coal miners in the country are reported to be getting ready for a strike to begin to-day.

IT is now expected that in the Senate deliberations on the tariff bill the duty on lead will be increased.

"THE Great American Pie Company of Chicago" is about to be placed in the hands of a receiver. There need be little difficulty in finding a receiver for pie.

THE down stage between Angels and Milton was held up in the regular orthodox fashion last Monday. Between \$1800 and \$2000 was got out of the treasure-box.

THE North American Navigation Company has ceased operations and will no longer vex the Pacific Mail Steamship Company. There is money enough on hand to pay all claims.

Mrs. PULLMAN of Fort Scott, Kansas, the only city woman treasurer in the country, is "short" \$1500 in her accounts. She is honest, but claims that her books have become "confused."

THE California First Division of the Industrial Army is walking through Illinois. The cry is still "Oo to Washington." The Coxy contingent are almost within sight of the national capital.

THE International Telephone Construction Company of Chicago has been incorporated for the purpose of building telephone exchanges for the Harrison Company, which proposes to revolutionize the telephone business.

THE strike on the Great Northern Railroad, which is a fight between two rival labor organizations, is still on, and the miners along the line of the road are being discharged by hundreds because of inability of the mining companies to secure ore transportation.

AFTER a thorough investigation the Secret Service pronounces as "absurd" the recent widely reported statement that counterfeiters had coined 500,000 real silver dollars at Omaha, which the authorities could not tell from the genuine output of the United States Mints.

THE registration bureau of the internal revenue department has already issued 38,000 Chinese resident certificates, with several thousand yet to apply. As the census shows but 35,000 Chinese in this district, it is evident that many thousands of Celestials have been smuggled in.

A NEW SEIGNIORAGE BILL has been introduced in the House, providing for the coining of the seigniorage and so amending the Resumption Act that three per cent bonds would in future be issued in lieu of four and one-half and five per cent. It is said to meet with Secretary Carlisle's approval.

THE franks at the Carnegie Works, wherein defective armor plates for the government cruisers were foisted upon the national officials, are to receive strict investigation. It was supposed the matter had been condoned by the payment by Carnegie & Co. of \$140,000, but a rigid investigation has been ordered by Secretary of the Navy Herbert.

THE United States is the owner of a rolling mill at Charlestown, Mass., and of another at Rock Island, Ill. The rolling mill at the Charlestown Navy Yard has recently resumed operations. Orders have been received to have the iron chain making rolled at this yard. The cable for the three new warships, Oregon, Massachusetts and Indiana, will be made there.

THE McGarrahan claim, which has been a national institution for the last thirty years, will probably cease to be a topic of congressional attention much longer. The famous claimant has been taken to the Washington, D. C., hospital in a state of physical collapse. Time was too much for him, and his famous career is but another illustration of the hopelessness of a case that awaits governmental favor.

THE United States Corporation Bureau, of Chicago, makes the following exhibit of new corporations incorporated in the United States during the month of March, 1894:

Total corporations, 1180.	
Total capitalization, \$182,130,860, distributed as follows:	
Mercantile and Manufacturing Companies, 668.....	\$52,779,525
Banks and Investment Companies, 16	707,000
Gold, Silver and other Mining and Smelting Companies, 92.....	63,681,000
Coal and Iron Companies, 17.....	3,015,000
Light, Heat, Power and Transportation Companies, 57.....	19,305,000
Building and Loan Associations, 31.....	19,173,000
Irrigation Companies, 12.....	428,500
Miscellaneous, 287.....	23,141,835

IT is proposed to ask Congress for legislation authorizing an investigation by the Labor Bureau into the influence of the use of machinery upon labor and the cost of production, the relative productive power of hand and machine labor, the cost of manual and machine power, as they are used in productive industries, the effect upon wages of the use of machinery operated by women and children, and whether changes in the creative cost of products are due to a lack or a surplus of labor or to the introduction of power machinery. No similar investigation has ever been attempted on any such scale of magnitude as proposed.

THE "stories of American manufacturers," which the Census Bureau is issuing in bulletins, is brought down in the latest number to manufactures and mechanical industries, each of which reported a product valued at \$30,000,000 or more during the year ending May 31, 1890. There are 287,501 establishments reported for the 67 industries presented in this bulletin, or 80.90 per cent of the total number of establishments in the United States. These establishments show \$5,249,139,842 of capital invested, or 80.45 per cent of the total capital for all classes of industry. They also report 3,370,557 employees, receiving \$1,311,188,882 wages, or 79.17 per cent of the employees and 79.34 per cent of the wages for all industries. The cost of materials used was \$4,373,402,066, or 82.84 per cent of the total materials of all industries. The value of product was \$7,618,836,200, which was 81.31 per cent of the total product of manufactures in 1890.

Method of the Capillary Electrolytic Sluice in the Extraction of Gold.

Written for the MINING AND SCIENTIFIC PRESS by J. H. Jory.

To Californians engaged in gold extraction the fact that under certain conditions of mining, milling and varieties of ore enormous losses in gold occur is well known; the causes of these losses are sometimes obvious, but are much oftener obscure, unsought for and unknown even by the mine superintendent. Without entering into any definite discussion at this time as to the amount of gold thus lost or the causes leading up to the result, I will only say that the loss is great and unavoidable under the established systems of extraction, and may be comprehended fully under the one term "float."

Coarse gold, whether in refractory or free-milling rock, or in hydraulic mines, may be saved by the present methods of milling and sluicing; but when the ore is crushed to such fineness as to liberate the minutely divided particles of gold, float is the resulting product, which can no more be saved by the old methods than can the motes that float in a beam of sunshine. That the arrastra, though slow and imperfect in method, is oftentimes far superior to the stamp mill in the percentage of value obtained, is well known and admitted. The reasons are not so well understood, though sufficiently clear when the process is considered. In the first place, the fineness to which the pulp is reduced in the arrastra liberates more of the precious metal than is usually the case in the stamp mill where the amalgamator has the fear of float before his eyes. In the second place, the stage at which the mercury is applied being that when the pulp is of the consistency of paste, renders unnecessary any reliance on gravity for the amalgamation of the fine particles. This catching at the straw of gravity being the futile aim of all established amalgamating methods except the arrastra, until the rise of the capillary electrolytic sluice produced a more scientific process. This new method takes hold of the operation of gold extraction at the critical point where the efficiency of the quartz mill and the hydraulic sluice leaves off, and saves all that is lost in those processes. In method it applies to flowing streams, containing gold in minute mechanical division that certainty of result now obtained in the analogous processes of electro-plating wherein fluids at rest containing metals in solution deposit those metals on the plates in circuit. Amalgamated copper plates set almost vertically in a sluice box in such a manner as to form capillary passages between the plates, are employed. The particles of precious metals held in suspension are forced into these passages and are gleaned from their containing fluids as completely as the particles of dirt are removed from the water when passed through the filter.

The capillary action caused by the contiguity of the plates is one essential feature of this process; that force increasing the affinity between the plates and the metal to be extracted. But the most powerful action of the sluice is the electrolytic force produced by passing a current of electricity through the series of plates and the flowing fluid containing the particles of gold. This action is twofold, first, in carrying and adhering to the plates every particle of gold, silver or mercury contained in the flow; and, second, in decomposing all films of oxides or sulphides that might otherwise prevent a free amalgamation. An alternating current has been found the most effective and satisfactory for this purpose, causing the precious metals to adhere to both surfaces of each plate free from all extraneous particles. The efficiency of this process in saving the fine gold from free-milling rock in quartz mills, beach mining and in hydraulic mining renders it of incalculable value in those operations, but in its application to the extraction of gold from refractory ores it is of still greater value, in that it will enable numerous mines to be worked at a profit that are now valueless.

It is not difficult of proof that gold exists almost universally in a metallic state, even in ores of the most rebellious character, and that the metal may be freed from its matrix by reducing the ore to a very fine state of mechanical division by mechanical means. Under the established systems, however, it is—as before stated—impossible to extract gold in this minute division from the slimes in which it is suspended, because it is almost unresponsive to the force of gravity. But in the capillary electrolytic sluice the forces employed act on particles not only of the finest mechanical division, but even on particles chemically divided, as demonstrated in electro-plating. The capillary passages of this sluice belong somewhere in the neighborhood of one-fiftieth of an inch in width, its capacity is, of course, limited to fine gold, and in the case of beach mining and hydraulic mining, screens are provided to remove the coarse sands from the flow before entering the sluice. This process does not, therefore, abolish the methods now employed, but is supplemental, except that such apparatus as sizers, concentrators and amalgamators may be entirely

dispensed with; together with the slow and costly processes of chemical extraction now employed.

There is but one element of cost entering into the process of the capillary electrolytic sluice above that of the simplest free-milling methods now employed, viz., the extra power required to produce the electric current, and the floor stamping of the ore requisite; when, however, the greatly increased product and the certainty of results are considered, this is scarcely to be thought of. But in the reduction of refractory ores the gain is so incomparable that a tabulated statement would appear almost incredible.

South Africa's Gold Fields.

From far-off Johannesburg, Ed Russell, who recently went there, writes to Thos. Winsor regarding that country concerning which there is so much present inquiry. He says:

"The labor market is now overdone in Johannesburg. Lots of men are lying around who have been unable to secure employment for months. Many of them are from Australia, and they have to borrow money to return home. A great many Americans also find it difficult to get anything to do, although they are preferred to almost any other class, especially in the mines. This is probably due to the fact that the principal mines are owned by Americans and operated by American managers. The only class of men safe in coming here are machloe men—good drill machine men, I mean, and good blacksmiths, of course. Carpenters, bricklayers, etc., might find work, but they are better away if they know when they are well off. Railway men are 'not in it,' as wages are low. I will say, however, that I think prospects will be better later. At present the best thing to do is to stay away. If one does want to venture, let him go to Natal, Delago Bay, or some other east-coast town. There the chances are much better, for the simple reason that everybody comes direct to Johannesburg."

"As to the climate, if you went to sleep to Arizona and woke up anywhere on the road between here and Cape Town, you couldn't tell the difference. About 300 miles from here you strike a splendid grazing country, all the world like northern California and southern Oregon. The soil is rich, red loam, and the climate similar to that of California. Johannesburg is 6600 feet above the sea level. We are now enjoying the rainy season, which is called summer. The winters, they tell me, are very dry and dusty, and heavy frosts are frequent. The country hereabouts is as level as a prairie, but New Johannesburg lies in the center of a hilly spot. This ridge is the much-talked-of gold reef, and is wonderfully full of free-milling ore. Dozens of mills are already in operation, and more are being erected. In a few years Johannesburg will be full of such mills, and there will be employment for thousands of men."

"The reef is 60 miles in length and runs north and south. Only the outcroppings have been worked so far, but arrangements are being perfected to work the lower levels, where the ore is said to run much richer. Each claim is 400 feet square. Those located on the outcroppings of the reefs are fast being worked out, owing to the dip of the reefs, so that owners of claims on the deeper levels will have to work under the greater expense. I understand that the majority of the mining claims and mills are owned by the Rothschilds; but be that as it may, there will be plenty of work for the poor man in the future. Just think of it! A city of 60,000 inhabitants, of which one-half are whites, formed in six years, and a very fine city at that. The blacks are industrious fellows, too, and do all the common labor at from \$15 to \$20 per month. The much-talked-of war is over for the present. The scene of action is about 600 miles from here, so that news reaches us very slowly. The impression prevails that just as soon as the dry season sets in and the floods subside the head chief will be on the warpath again."

"With the advent of the dry season there will be a grand rush for Matabeleland, which is reputed to be the richest gold district of South Africa. It is said to be a dangerous trip on account of the fever in the lowlands, through which one must pass in order to reach the promised land. The charter company is attempting to get control of the entire district, and already lays claim to one-half of all mineral found there. The Government backs it up, and is making it warm for prospectors and locators."

"In this city good board can be obtained for \$7 per week. The bill of fare includes plenty of beef and mutton, but very few vegetables. The Boers are too lazy to raise vegetables, and the result is that potatoes are worth from \$4.50 to \$5 per cental. Ham costs from 60 to 75 cents per pound, and eggs 60 cents per dozen."

In 1842 the British customs tariff numbered 1200 articles. Now it contains but 19, the principal of which are tobacco, tea and liquor.

A Field for Young Men.

John B. Tregloan, in Midwinter Fair Edition of the *Amador Record*.

In choosing one from several topics that had occurred to me, I tried to bear in mind two points—first, what would be of the greatest interest to those who may read this article, and, secondly, to confine myself to a topic that would promote and do its humble part in making Amador county a great mining district—great in the degree that the Comstock mines of Virginia City were great, and akin to the gold fields of Africa. Gold mining, as an industry, and more especially deep or quartz mining, is in its infancy—as markedly so in this county as in any locality in the United States, and probably in the world.

For a distance of 12 miles along the mother lode, from the Empire and Pacific at Plymouth to the Kennedy near Jackson, there are between 40 and 50 properties. Of these but eight have gone below the 1000-foot level. Six or seven have reached the 900-foot level, two or three to the 700-foot level, while the remainder have been untouched and remain to-day virgin properties. Of the four mines opened up below the 1000-foot level, every one has yielded its millions, and two of which are doing so to-day. To the east and west of these different locations there are several claims, perhaps twice as many in all. So much for the field to work in, and now a word as to the outlook for new properties being opened and developed.

Each day brings its quota of mining men to the county. Many of them are looking for good investments for themselves, while others are acting as agents for companies and individuals. Properties are being bonded right along, prospecting is being pushed ahead and new veins are being discovered. The mines throughout the county are yielding over \$100,000 per month in free gold, not counting the amount realized from sulphurets. The resources are such that this could be doubled if the ore were hoisted to the surface and milled, which, unfortunately, is hindered by the lack of necessary equipment. Amador county has a future that will cast a shadow over any other county in the State within the next five years. The great need up to the present time has been "capital and courage" to make the necessary developments, and, I am pleased to note, the fact is becoming well known. Interested parties are now aware that the hills and valleys along the mother lode contain fortunes for those who will seek them. We have seen what the county has done, as well as what it is doing, and we flatter ourselves on the bright outlook of the future.

Mining is becoming more and more of a science, and yet the methods of working are becoming simpler. Improvements are constantly being made in appliances, and progressive mining men are constantly on the lookout for improved methods of saving the gold from the ore. Mining is a broad field for young men to distinguish themselves in. If they are intelligent and observant, and possess any mechanical genius, they can find many avenues in mining in which to profitably train their abilities. Every mine should have an assayer; photography is going to enter into the work, for the peculiar mineral formations and changes must be preserved through this agency for future reference and study; then there must be a surveyor and bookkeeper, and the future mining superintendent will have to be qualified, to a greater or less degree, in all these branches. The young mining engineer should find his post-graduate work in a mine, and not in an office where only theoretical views can be obtained. In this way he can qualify himself to take the place which must soon be relinquished by an older person. No position requires greater executive and practical ability than the successful superintendency of a gold mine, and none is more honorable.

IT IS TELEGRAPHED from Washington that Senator Carey is encouraged over the prospects of the passage of the bill for the cession of 1,000,000 acres to each arid land State and Territory, to be improved by irrigation. The general expression of opinion by members is in favor of the bill, and there is little doubt it will be favorably reported soon by the Committee on Public Lands. Mr. Carey believes the bill will receive the unanimous endorsement of the committee. Senators Dolph and Vilas favor the bill, and say it provides for an experiment in the right direction and may lead to the solution of the question, "What shall be done to reclaim the arid lands?" The far Eastern people probably will favor the idea, as they seem to be possessed of a constant fear that Uncle Sam will spend something himself in improving these lands. Rather than do this, they prefer that he should give them away. But it is quite a question whether the sons of these Eastern men, when they desire farms in the West in the next century, will think their ancestors were so wise to let all these lands go to private ownership to which they must pay rewards for holding. The Eastern person does not understand the West, nor does he seem to be making any progress in that direction.

The Pyritic Smelting Process.

IN TWO PARTS—PART II.

By Philip Argall, E. M., in *Engineering Magazine*.

Another familiar example is the burning of pyrite in kilns for the manufacture of sulphuric acid from the gases given off. In these kilns the pyrite is burnt at a cherry-red heat at the rate of about 40 pounds per square foot of grate area, or say 50 square feet of grate area per ton of ore burnt per day. A modern pyritic-smelting furnace would easily consume 100 tons of pyrites per day in the same area. Now, as temperature is, within certain limits, directly proportional to the amount of fuel consumed on a given area in a given time, one will readily see, by analogy, the enormous temperature that can be produced by the oxidation of pyrite in such quantities. In this way, the possibility of pyritic smelting becomes manifest even to the uninitiated.

From an examination of the available literature of the subject I am led to the conclusion that the inception of smelting pyrite by its own combustion came long after Bessemer's invention for the direct manufacture of steel, by means of blowing air, divided into numerous jets, through a bath of molten cast iron, thus effecting the rapid oxidation, or combustion, of carbon, silicon, and certain other substances present in pig iron. In this process it is obvious that the high temperature developed in the converter is the result of the intimate contact between the air and various oxidizable bodies present. To substitute a molten copper-iron matte in the converter for the cast iron, and to oxidize the iron and sulphur of the matte, producing "black copper" in one operation would appear to be a natural development of the Bessemer idea, and one that, at the first glance, appears to be very easily carried out. Nevertheless, the first experiments in this direction, made in Russia in 1867, resulted in complete failure, as did also the attempts of Mr. John Hollway to smelt pyrite in a modified Bessemer converter, in England, in 1879. M. Pierre Manhes, however, in 1881, succeeded in the bessemerizing of copper matte, overcoming the difficulties of the earlier experimenters, and established his process on a working basis in France. This Manhes process, with various modifications and improvements, is now extensively used in this country for the treatment of copper mattes—of low contents in precious metals. I look upon the Manhes process as pyritic smelting carried to a conclusion by the more or less complete oxidation of the iron and sulphur, and the production of almost pure copper (98 to 99 per cent fine) from the ordinary copper matte.

Returning to pyritic smelting proper, the experiments of Hollway proved that it was possible to smelt pyrite by means of the heat developed through its own combustion. But many obstacles and difficulties were encountered, some of which proved insurmountable, and in consequence of which continuous smelting could not be carried out in the apparatus then used. And while the experiments excited much interest at the time, it was generally conceded that as a commercial system of ore reduction the whole process was a failure.

Mr. W. L. Austin, of Denver, for some years past has given this subject of pyritic smelting much thought and attention, subjecting his methods to careful and thorough tests on a working scale, until he has succeeded finally in overcoming the difficulties encountered by the earlier workers in this field, and, with the aid of the most modern improvements in metallurgy, has built up a system of pyritic smelting that has taken firm root in Colorado, and has become a great industry in the land.

The furnaces used in carrying out the Austin system of pyritic smelting closely resemble the blast furnace used in lead smelting; differing, however, in some essential particulars which are necessary to fit it for the use of the sulphides as fuel instead of the carbonaceous material employed in the lead furnace. The capacity of the pyritic furnace is, however, from 30 to 50 per cent greater than that of a lead-smelting furnace of the same dimensions. This may be partly explained by the fact that in the former the ore and fuel are united in the one substance, *pyrite*; consequently no space is occupied with coke, nor is any time wasted in burning this bulky material.

The *modus operandi* of a pyritic furnace consists in feeding the raw ores and fluxes in pieces as large as can be conveniently handled—and, of course, of the proper composition to form the desired slag—and drawing off the products of the smelting operation, matte and slag, either continuously, as in the case of large furnaces, or at regular intervals in the case of smaller ones. The matte resulting from the first smelting is usually put through the furnace again, together with rich silicious ores. This matte is, if anything, a better fuel than the raw pyrite, and by this second process it is concentrated to a very high value in precious metals, and is then shipped to the refiners. It is, of course, understood that the raw, unroasted pyritic ores

are used in the pyritic smelting furnace, while in other smelting processes such ores must be calcined—often at great expense—before they can be smelted. In the pyritic process, then, the ores are, as it were, roasted and smelted in one operation, at a cost very little in excess of roasting the ores by hand labor.

A word explanatory of the theory of this interesting system of smelting may be permissible. As the pyrite, FeS_2 , descends the shaft of the furnace, one atom of the sulphur is expelled when the zone of dull-red heat is reached. This atom, on meeting the air at the surface of the charge, burns, with the characteristic sulphur flame, to sulphurous acid, SO_2 . The pyrite, then, deprived of its extra atom of sulphur, reaches the zone of fusion as mono-sulphide of iron, FeS , and here it is immediately oxidized by the highly-heated air blast to ferrous oxide and sulphurous acid. The former, combining with the silica, forms a slag of ferrous silicate, while the latter ascends the stack with the other gases. As there is always more or less mono-sulphide present than can be oxidized by the blast, the sulphur runs down in the form of iron matte, which contains practically all the precious metals carried in the furnace charge. If the furnace is worked with a closed top, sulphuric acid may be manufactured as a by-product from the gases evolved from the smelting operation.

In lead or copper smelting, ores rich in these metals are smelted for a moderate price per ton, while the ores that require the addition of lead or copper to the furnace charge, in order to beneficiate them, are naturally subject to a much higher rate for treatment. The supply of such ores in Colorado has been for some time in excess of the available quantity of lead and copper ores necessary to treat them. Leadville, for example, for many years the center of the lead-smelting industry, and even now the greatest producer of lead-fluxing ores in this country, did not yield sufficient lead last year to treat more than one-half her own output. It would therefore appear that there is a good opening in Colorado for a smelting system that can reduce "dry" ores without lead or copper, or with but little copper. Such a system is found in pyritic smelting, by which the precious metals are reduced from their ores by means of the very common, cheap but nevertheless useful metal, iron.

Pyritic smelting is not only applicable to the reduction of the ores of the precious metals, but it can also be applied to the treatment of miccoliferous pyrrhotite, or cupreous pyrite. The raw ores in each case would be fed direct to the furnaces together with the necessary fluxes, the resulting matte could be drawn off into converters and blown until the desired concentration is reached. The whole process of making black copper from the ores should not, under favorable conditions, and conducted on a large scale, exceed \$2.50 to \$3 per ton of ore treated.

Pyritic smelting is comparatively new in Colorado. It is just two years since it was introduced at the La Plata smelter at Leadville, yet we find two works running under the system last year, treating, according to the published statements, over 55,000 tons of ore, producing therefrom 494 tons of copper, 6165 ounces of gold, and 1,224,026 ounces of silver. The product of these works is, as we have seen, an iron matte containing some copper. Now, as the iron in the matte is of little commercial value, it is not estimated in the yearly statement. Taking the copper for comparison, however, we find that, for each dollar's worth of this metal produced, over \$11 worth of precious metals were collected from the ores, against $6\frac{1}{2}$ to 1 in the typical lead-smelting example given herein.

A process that can obtain such remarkable results within two years of its introduction into a State that holds the proud distinction of leading the world in the metallurgy of the precious metals, shows at once its great metallurgical value as well as its economic importance. And it augurs well for its successful introduction into other countries less highly favored with smelting works than Colorado, but which have more extensive deposits of available metallurgical fuel in the form of pyrite. This ore occurs in almost every mineral vein, is more or less abundant in every country, and is now through this process rendered valuable, both as fuel and as a vehicle for smelting and collecting the precious metals from their ores.

THE Bakersfield, Kern county, *Standard* says: There are many persons here who propose to go to the gold fields in the desert when the time arrives that work can be pursued to advantage. We do not believe that persons out of employment can do better than go. There is no doubt that an industrious man can make some money there, a little certainly, if not a good deal. Might not something in the way of gold-hunting be done nearer home? We are told by old residents that many years ago, before gold-digging in the State was generally abandoned for other fields of endeavor, that much placer mining was done along the end of Kern river, from the old overland stage crossing upward. At that time, along the edge of the river, a pair of miners

industriously operating a rocker on gravel taken from the banks was a sight of frequent occurrence, and it should be remembered that an ounce of gold dust is worth as much as four were then. If there are any old miners here we hope they will investigate a little before going farther hundred men might work along the river from the stage crossing to the canyon, with rockers, without raising a debris question, provided gold in paying quantities were found.

Limestone Made Into Marble.

Various modes of coloring limestones have been developed, but the latest that has come under our notice is described in a recent number of *Engineering* as follows:

Marble is a natural product, so that this title is perhaps inadmissible; but works have just been started at Chelsea in which the natural process is so closely imitated by chemical means that there is produced so near an approximation to marble as almost to justify the name. Nature's process is hastened, and is more directly under control, so that although the veining may be varied as art demands, there can be a large production of a uniform tint of stone if desired. The process known as the Moreau-Rae is simple; and by it all limestones or chalk may be converted into the semblance of marble of any tint or combination of shades, while the specific gravity is increased 25 per cent. With limestone, carving or turning is more easily done than with marble. The first process thereafter is to prepare for veining. On the surface of water there is sprinkled a varnish composed of sesquioxide of iron, gum thus and turpentine; and water being unstable, a freedom of design is obtained, especially when the turpentine is broken up by sprinkling of soap. The stone is dipped on the turpentine and subsequently immersed in baths of metallic solutions. These are of sulphates of iron, copper or zinc, separate or in combinations, the specific gravity varying from 1.2 to 1.5. They may be termed the primary colors, and variety of shade is got by different periods of immersion or in varying the order of tanks used. The varnish prevents the sulphates affecting the stone at those points, according to the density of the varnish.

In the case of some French stones where there is a good deal of shell or flint, this process of artificial veining is not necessary, as the same result is got from the existence of shell, and this Marseilles stone has been made into very effective balustrades, as well as fireplaces and table tops. Very dark colors, for instance, are got by using copper and iron sulphates. Zinc and iron alternately give light yellow, while the use of the three in turn gives dark yellow and brown in variegated tints. Black and gold, too, may be got by making the stone yellow before varnishing, after which the black bath is used, so that the veining takes the gold tint. Infinite variety is possible in the manner indicated. After this treatment in the sulphate baths, the stone is immersed in a water bath maintained at 50° Cent. to thoroughly fix the colors, all air meanwhile being expelled; and here it may be stated that the color permeates the full thickness of the stone, as is shown by blocks cut into several thicknesses. The process thus far takes only a few minutes, and the stone is then dried in an oven of a temperature of 90° to 100° Cent., remaining probably for 24 hours. It is then immersed for a corresponding period in an indurating bath—in a solution of sulphate of zinc—which does not affect the color, but effectually hardens the stone, closing up the pores, so that when removed it approximates the density and the specific gravity of marble and has all its beauty and wealth of coloring. It is afterward polished in the usual way.

Advance in Explosives.

In the explosive known as nitro-glycerine a most logical advance was made in explosive science, says an exchange. This is the most intense chemical union which can be placed under practical control that is known to the present conceptions of chemical science. What we know as dynamite, ebensite, gelbrite, etc., whatever secrecy their discoverers may claim for the two latter and others not mentioned, these are virtually dilutions of the first mentioned, the nitric element being the potent element in all of them. In the case of dynamite, it is not necessary to start with the highest grade of explosives; and the introduction of foreign ingredients, in the process of dilution, even then is carried to beyond 75 per cent. This is to insure greater safety in handling, and the substance still possesses all the force necessary to overcome the resistance against which it is intended to act. But let us now consider this simple but amazing combination known as nitro-glycerine. Glycerine is a sweetish substance that forms the basis of fatty matter. The liquid is transparent, without color or smell, and of the consistency of a thinish syrup. This is not even necessary, as a most terrific grade of explosive can be secured by substituting common lard oil. The

basis of nitric acid is oxygen and nitrogen, five equivalents of the former to one of the latter. Oxygen is the vital part of the atmosphere and supporter of combustion and has a peculiar property in generating acids. Nitrogen is the principal ingredient—the vehicle—in atmospheric air—a colorless gas, devoid of taste or smell.

Beet Sugar Interest in the United States.

The production of beet sugar is now receiving so much attention in this State that many readers will be profited by a general review of the industry in this country and a descriptive narrative of the ways and means employed. Dr. H. W. Wiley, who is at the head of the Division of Chemistry of the Department of Agriculture and has immediate charge of the sugar experiments and investigations made by the Government, has the following admirable article, of the scope indicated above, in the April issue of the *Engineering Magazine*:

The beet-sugar industry in the United States is in its infancy, there being only seven manufactories of this product in operation in this country. The oldest of these, at Alvarado, California, was erected about 15 years ago, and has been operated every year since. The factories next in order in seniority are those at Grand Island, Nebraska, and Watsonville, California. Still younger than these, by one year, are the factories at Norfolk, Nebraska; Lehigh, Utah; and Chino, California. The youngest and smallest of the factories, located at Staunton, Virginia, has been operated only one season. The increase in the rate of beet-sugar production in the United States during the past few years is shown as follows:

	Pounds.
In 1887.....	600,000
In 1888.....	4,000,000
In 1889.....	6,000,000
In 1890.....	8,000,000
In 1891.....	12,004,838
In 1892.....	27,083,288
In 1893.....	43,648,797

The next table gives the production, during 1893, at the different factories, as follows:

	Pounds.
Staunton, Virginia.....	36,458
Grand Island, Nebraska.....	1,835,900
Lehigh, Utah.....	3,750,000
Norfolk, Nebraska.....	4,000,000
Alvarado, California.....	4,486,572
Watsonville, California.....	14,500,000
Chino, California.....	15,036,867

The amount of capital invested in the seven beet-sugar factories is about \$2,000,000. Tributary to these factories, under cultivation in beets, are about 20,000 acres of land. The value of this land has greatly increased since it has been used for beet-growing, especially near Chino, California, where the price per acre has become very high, as much as \$200 having been paid in some cases. The cost of cultivating this land in beets is considerably more than \$500,000 a year. The production of beet roots for sugar-making purposes in the United States during the past year approximated 200,000 tons, and the average price paid to the farmers for this raw material was \$4.50 per ton.

It will be seen that a large investment of capital in land and machinery and a large outlay of money for labor are needed to produce a little over 200,000 tons of sugar per year. It is not difficult to foresee the large amount of capital that would be absorbed, the immense amount of labor that would be employed, and the great extent of land that would be placed under cultivation, if even half of the sugar consumed in the United States were made from beets grown within the country. The yearly consumption of sugar in the United States is now approximately 2,000,000 short tons, while the total production of all kinds of sugar—beet-root, cane, maple and sorghum—is about 300,000 short tons, showing that a little less than one-sixth of the total amount consumed is produced at home.

The manufacture of beet sugar in this country is a matter for serious consideration. By reason of the restricted area suitable for the cultivation of sugar cane, it is not to be expected that, under the most favorable conditions, the production of cane sugar in Louisiana, Texas and Florida will ever largely exceed 1,000,000 tons. On the other hand, there are no limits to the possible amount of beet sugar which can be manufactured.

BET FARMING IS HIGH-CLASS WORK.

The production of sugar beets is of itself an art. The ordinary forms of agriculture cannot be used for this purpose. Sugar-beet culture is in every sense intensive, and not extensive, farming. High-priced lands can be used for sugar-beet culture on which it would be impossible to grow profitably the staple crops. Intensive culture, high fertilization, and scientific care in every respect characterize successful beet-sugar culture the world over. The sugar beet requires a deep mellow soil, perfect tilth, entire freedom from weeds and grass, and a great deal of hand-culture. The sugar beet absorbs large quantities of water in its growth; it is fond of potash and phosphoric acid, and is not averse to nitrogen. It is a crop which should not be grown more than once in four years upon the same field, and this field, by judicious rotation and fertilization, is brought during this time into perfect condition again for the production of a maximum crop of beets. The establishment of beet-sugar culture in a community gives an object-lesson in the highest art of agriculture. It acts reflectively upon every other branch of agriculture, so that in countries which grow sugar beets there are better crops of wheat and maize, of barley and hay; there are better classes of live stock, finer horses and cattle, and in general the whole tone and character of agriculture are elevated by reason of the influence, direct and reflexive, of the culture of the sugar beet.

The sugar beet has been brought to its present state of efficiency by the application of scientific principles of

culture in the production of seed. The mother beets selected for seed the previous year are chosen on account of their perfect form and size. They are preserved during the winter in silos. In the early spring they are removed and a diagonal core taken from each one is analyzed. The beets are in this way separated into grades; those showing above a certain percentage of sugar forming the *elite* or first grade, those falling within another class the second grade, with a third class lower, while all those which fall below the standard fixed for the lowest grade are rejected. Little has been done in this country in the way of the production of beet seed, but for three years the United States Department of Agriculture has grown the highest-grade seeds at its station at Schuyler, Nebraska, in accordance with the principles set forth above. The careful experiments undertaken by the Department at this station at Schuyler have shown that beets quite equal to the best grown in Europe are easily produced in the United States.

HOW THE BEETS ARE HANDLED.

The sugar beets, which mature in September or October, are carefully harvested, and the foliage, with a portion of the neck of the beets, removed by a knife. Each beet must be handled separately for this purpose. A portion of the top of the beet is removed because that portion contains a large percentage of the salts found in the beet. These salts—chiefly potash—exert a very injurious effect upon the sugar juices during the process of manufacture. They are bitter; they unite with any oil which the beet may contain and form soap, and they prevent large quantities of sugar from crystallizing.

The sugar beet, having been brought to the factory prepared as above, is passed through a long trough by means of a screw, through which water flows in the opposite direction from the movement of the beets. The beets are thus thoroughly cleaned, all fragments of soil and pebbles being detached therefrom. Thorough washing is highly important, since the presence of sand, or soil, or grit of any kind upon the beets when they reach the cutting machine rapidly dulls the knives and produces bruised and imperfect cuttings. The beets, having been washed, are elevated to a cutter immediately over the diffusion battery. This cutter is a horizontal disk, carrying several corrugated knives. These knives slice the beets, usually into V-shaped pieces, so that, when placed in a trunk, water may freely circulate among them.

The beet cuttings, called "cosettes" or "schnitzel," are next conducted to the diffusion battery—a piece of apparatus designed for the extraction of sugar by means of the osmosis of the sugar juices with the water which is brought into contact with the beet cuttings. The diffusion battery consists of from 12 to 14 cells so arranged that a liquor can be passed at will from one to the other and drawn off from any one of them at any time. The hot water which is used for the extraction passes from one cell to another, becoming more and more charged with sugar juices. When it has passed through a sufficient number of cells—usually 10 to 14, according to the size of the battery—it reaches finally the cell last filled with beet cuttings, and from this it is drawn off into a measuring tank. When the battery is once filled its operation is continuous, one cell being filled with cuttings and the exhausted cuttings being discharged from another every time a portion of juice is drawn into the measuring tank. The exhausted pulp is passed through a press by means of which a large portion of the water is forced therefrom, and the residue makes a most excellent food for cattle. This ration, however, is not a well-balanced one, and certain nitrogenous and fatty bodies are mixed with it in order to make a perfect food. Oil cakes are very suitable for mixing with exhausted pulp for this purpose.

The sugar juices, withdrawn from the battery as above mentioned, are passed into large tanks, where they are saturated with lime, from one to three pounds of which are used for each hundred pounds of juices. The temperature of the mixture is then raised gradually, and meanwhile a stream of carbonic acid is blown through the mixture. By this treatment the lime is precipitated as carbonate of lime, carrying down with it a large portion of the impurities originally contained in the beets. Beet juices, when first extracted, are usually of a dark, almost inky color. After treatment with lime and carbon dioxide in the manner above described, they are usually perfectly brilliant and of a beautiful amber tint. After the lime is all precipitated the juices are passed through filter-presses, on the cloths of which the lime and impurities are retained while the bright juices run through. A second treatment with lime and carbon dioxide is uniformly employed, and sometimes a third, in order to secure sugar juices of high purity. The carbon dioxide used for this purpose is derived from a lime-kiln in connection with the factory, which also furnishes the lime necessary for the precipitation of the impurities.

The purified juices, treated as above described, are next conducted to a multiple-effect evaporating apparatus. Here the juices are concentrated to syrup, the vapors from one of the multiple effects being used to boil the liquor in the second, and the vapor from the second being used to boil the liquor in the third. When this apparatus has two pans, it is called a double effect; when three, triple; they rarely contain more than four, while three is usually the number found.

The syrups, treated as above, if only raw sugar is to be made, are carried directly to the vacuum-strike pan. Small quantities of syrup are first taken into the pan and reduced to the crystallizing point. When fine crystals of sugar appear, additional portions of the syrup are drawn into the pan, continuously or from time to time, and the small microscopic crystals first formed begin to grow to the required size. The operation usually requires from three to sixteen hours, according as the pan is a quick or slow-boiling one.

The sugar thus crystallized during the process of boiling is removed from the pan into a mixing apparatus, where it is thoroughly mixed by means of revolving arms. It passes then directly into the centrifugal apparatus, which, having perforated sides and revolving with great rapidity, quickly removes the molasses from the crystals, leaving

the latter in a very dry form and suitable for transmission to the refinery.

In some beet-sugar factories the refining is done during the process of manufacture. In this case the syrups, before concentration, are filtered through bone-black or saturated with sulphurous acid. By these methods a pure white crystal of sugar is obtained, which, on being dried in a granulating apparatus after coming from the centrifugal, forms granulated sugar.

The molasses which is obtained by the above process is reboiled, and a second crop of crystals obtained therefrom. The molasses from this second crop of crystals is reboiled, placed in tanks, and left to stand for five, six or even eight months, at the end of which time another crop of crystals, dark and mushy, has been formed, which can be separated by the centrifugals in the usual way. The final molasses, which contains a considerable quantity of sugar, is used either for distilling purposes, for fertilizing purposes, on account of the large amount of potash which it contains, or it may be subjected to treatment with freshly burnt and ground lime, at a low temperature, in which way the sugar which it contains is precipitated as sucrose of lime, from which the other impurities can be separated. The sucrose of lime can afterward be beaten up with water into a paste and the lime precipitated with carbon dioxide as above described for purifying the juices. In this way almost all the sugar which was present in the molasses can be recovered.

The manufacture of sugar is a continuous process, *i. e.*, the operations go on day and night. It is probably 24 or 48 hours from the time the beets enter the factory before the crystals of sugar secured therefrom appear, and the process is of such a nature that it cannot be broken except, usually at the end of a week or two weeks, when the house is shut down for repairs or renovation. An ordinary beet-sugar factory has a capacity for the consumption of about 250 tons of beets per day, and should make from 200 to 240 pounds of sugar per ton. In Europe, larger factories are very common, capable of working from 400 to 600 tons of beets per day. In central factories there is a large number of diffusion batteries situated at different points, in which the juices are extracted. From these different places the juices are delivered to the central factory by means of pipe-lines, usually laid under ground. A central factory of this kind will be found able to take care of the juices from 1000 tons of beets per day.

Every one who desires to see the prosperity of American machinery, American ingenuity and American agriculture should favor the development of the beet-sugar industry. There is no other way in which the plethora of agricultural products can be so readily relieved and renewed prosperity brought to our agricultural interests, thus stimulating every other interest in the land. The total consumption of sugar in the civilized world is not far from 7,000,000 tons, of which the United States uses two-sevenths. Of the 7,000,000 tons, over 4,000,000 are made from sugar-beets. It is thus seen that in the race for the markets of the world the sugar-beet is already ahead of its most dangerous rival, the tropical sugar-cane. There is room, however, for both these sugar-producing plants, and there is reason to believe that, with favorable conditions, a great indigenous sugar industry, including cane and beet sugar, can be established in the United States.

African Diamonds.

The African diamond fields are in the Orange Free State, where there is one important mine at Jagersfontein, and in the British colony of Griqua Land West, where there are four, says the *Scientific American*. Of these, the best known are the Kimberley mine and the De Beers, the latter of which was so admirably illustrated in last summer's Columbian Exhibition.

It is but 25 years since the gems were discovered on the Dark Continent, and the value of the annual yield now exceeds \$20,000,000. It is interesting to note that notwithstanding these large quantities are mined and that diamonds have been so successfully imitated, their value has not declined more than a dollar a carat.

The South African mines have yielded larger stones than any found in Brazil or India. Some of them are of a yellow tint, and therefore of low value; but the De Beers diamond (428½ carats) and the Jagersfontein (969½ carats), the last found less than a year ago, are perfectly white. These weights are for the rough diamonds, but the Kohinoor weighed only 192 carats, and was reduced by cutting to 102½ carats.

The Kimberly mine has been worked to a depth of 400 feet, and vertical shafts have now superseded the inclined ones formerly used as means of entrance.

The quantity and value of the African gems in the market have made great changes in the diamond trade. The Brazilian gravels are now worked very little, as are the fields in India and Borneo. London is the diamond market of the world.

Warns Against Fire Damp.

A sonorous warner against the appearance of fire damp has been invented by M. Somzee, and was commented upon at the last meeting of the Paris Academy of Sciences, by M. Haton de la Goupilliere, director of the Paris School of Mines. The invention is brought into action by a flame, under pressure of which a tube vibrates and sounds a warning as soon as the fire damp is present in a working, and in the opinion of M. de la Goupilliere the apparatus should be adopted in mining operations and would be found of great service.

Marble Product of California.

J. H. Giles in the Midwinter Fair Edition of the *Amador Record*.

California is not a whit behind her sister States in marble production. Inyo county has a world-wide fame for valuable marbles in large beds. Marble of fine quality, beautifully variegated and susceptible of a high polish, abounds on the Middle Fork of the Feather river in Plumas county. Our neighboring county of El Dorado, where marble quarries were first opened in California at Indian Diggings in 1857, abounds with marble of excellent quality. There are 30 marble beds, more or less, developed, which give promise of becoming valuable quarries. Almost every variety of marble known to the trade may be found here. One of these deposits, at Grizzly Flat, is of pure white, unclouded marble and is of such extent that immense blocks may be quarried; indeed, it is said to be 600 feet in thickness. Within this magnificent marble bed there exists an extensive grotto, consisting of a succession of large rooms, connected by narrow passages, and extending in length, in the aggregate, 700 feet. Some of

worth. It is of the serpentine or verd antique, green-veined marble—a most rarely choice stone. Judging from the outcroppings, the neighborhoods of Mount Echo and Ione will doubtless some day develop new treasures of marble, while near Sutter Creek, on the ranch of James Elkins, Esq., a splendid bed of first-class, darkly veined and clouded marble has been unearthed; it is susceptible of a brilliant polish and in every respect ranks with the best. In several other places up and down Sutter Creek marble interests are developing.

The value of these deposits is at present not great, but in the future it will be immense. To render them of value to their owners, and to inspire others to prospect the country for other valuable beds, two conditions are requisite, viz., an increased demand for the marble and easy and cheap transportation. To increase the demand, let it be known far and wide what we have to sell; let the owners of these beds invite capital to assist in their development, and hold out such inducements that capitalists may see a profitable investment in accepting the invitation. There should be no "dog in the manger" policy pursued here;

Hawaiians at the Fair.

The Midwinter Fair is giving the average visitor the chance to see more outlandish people in a day than he might otherwise behold in the course of his natural life. These distinguished foreigners are variously engaged at the fair, but they are not here for their health; they are on hand to sell something, or a sight of something. This does not, apparently, diminish their popularity, and really they add much to the entertainment features of the fair and something to the educational features as well, for they fetch foreign customs, habits, dress and dwellings as well as can be learned anywhere outside of a school geography.

The engraving on this page shows a portion of the interior of the Hawaiian village, which is supposed to illustrate native life and manners. There are really many curious things displayed, ranging all the way from idols to industries. One of the most interesting parts of the exhibit is the pond and its appurtenances, which are shown in the engraving. In the foreground is a native in a native war canoe, with the peculiar outrigger which prevents the

INTERIOR VIEW OF THE HAWAIIAN VILLAGE AT THE MIDWINTER EXPOSITION.

these chambers are quite lofty, and from their roofs hang numerous stalactites, imparting to them, when illuminated, a bejeweled appearance of transcendent beauty.

Tuolumne county has long been supplying the market with much marble of the pure white, blue-veined and clouded sort, of good quality. Butte county also contributes a liberal quantity of the same general character as Plumas, the beds, like those of the latter county, being situated on the banks of the Feather river. In Placer county a vein of black marble of the variegated type, which is extremely rare and of great value, was discovered long ago. Solano county has uncovered, in the hills near the Suisun valley, a vast bed of most peculiar marble. In its crude, unpolished state it resembles rosin, but it is of pure quality, takes a good polish, and is thought by some to be but the outcroppings of a most valuable deposit of the rare and costly Sienna marble.

Last, but not least, our own little Amador is also rich in marble deposits of rare quality and beauty. Near Dayton, many years ago, an extensive quarry of white marble, slightly veined, was opened and was largely drawn upon by San Francisco for building purposes. At Oleta several valuable marble beds exist, and a marble mill between that village and Plymouth is in constant operation during the summer. Good marble beds abound in the neighborhood of Volcano. Near Willow Springs, on the Sacramento road, that enterprising citizen, Dr. Boyson, is now developing a marble quarry which promises to be of great

let the owners and their friends get out marble and send samples everywhere where it will do good.

As to the transportation, that matter is to be greatly assisted in the near future, it is confidently hoped, by the construction and operation of the Ione and Sutter Creek railroad. When this is accomplished, marble works can be constructed here and marble merchandise, equal to any and superior to much of the marble in the market, can be shipped from "Little Amador" to all parts of the world.

FIFTY-DOLLAR GOLD PIECES were never coined by the United States Government; there were, however, private issues of octagonal gold coins of this value in California in 1851, 1852, 1853 and 1855. In 1851-55, also, round fifty-dollar pieces were issued in California. They received their full value when deposited at the United States assay offices. By the now-existing laws of this country there can be no revival of private coinages bearing such close resemblance to authorized mint issues.

A HOLLOW celestial globe of copper at Pembroke College, Cambridge, England, was constructed in the last century as a lecture-room, and will hold a half dozen persons or more. The constellations are depicted on its interior, and it rotates on its axis.

MULHALL estimates the number of individuals who emigrated from Europe in 72 years, 1816 to 1888, at 27,205,000. Of these, 15,000,000 came to the United States.

canoe from rolling over. In this pond the native now posing in the canoe is supposed to play with the man-eating shark, when the shark arrives from Honolulu. It is said that this native Hawaiian is absolutely not afraid of sharks, for his father before him prayed to the shark gods that they would always protect his son from these monsters, and his prayer has thus far been answered, for he makes a dive, strikes out toward a great shark, moves around him, plays with him and has complete control of the situation. He is dark and muscular, and wears, when the weather permits, only a malo, or short apron made of grass. The great secret of course, in his skill, lies in his expertness as a swimmer and diver, encouraged, no doubt, by the faith in his father—and the gods. But how a man-eating shark can maintain any appetite for anything after soaking for a while in the Hawaiian village pond, passes our comprehension.

FREDERICK HUDSON says that the first printed newspaper was the *Gazette*, published in Nuremberg in 1457, and thereafter at intervals. In 1534 appeared in the same city the *Neue Zeitung aus Hispanien und Italien*, and at a date between these two appeared the *Cologne Chronicle*. These early newspapers are not contained in any library, so far as Hudson indicates; the earliest printed newspaper in existence is called the *Gazetta* of Venice, is dated 1570, and is represented by a few copies in Venice in the Magliabecchian Library.

Mechanical Progress.

New Machine Guns.

A special to the New York *World* says: Frank M. Garload of this city has finished, after five years' labor, two machine guns of which great things are expected, and he is backed by a syndicate of New Haven and Philadelphia capitalists. Arrangements are being made for a public trial soon near this city. At a private trial a number of army officers and ordnance experts from Washington and Philadelphia were present.

The larger of the two guns is a combination rapid-fire gun. It has three barrels, arranged so that the muzzles form a triangle. The upper one is a one-pounder and the other two half-pounders. The three barrels are cased in a bronze jacket of about 18 inches diameter and 4 feet in length. The mechanism for loading and firing the rifle is concealed in the case and protected from smoke and dirt. The mechanism is operated by means of two cranks, located on the right side of the gun. The one operating the larger barrel is about the center of the jacket; the one that loads and fires the other two is at the breech. Just under the center crank on either side are two hoppers, from which the two half-pounder caliber barrels are fed with ammunition.

The one-pounder barrel is hung on trunnions and tilts. A quarter turn of the crank raises the breech and ejects the empty shell. This is accomplished by means of an oscillating breech-block, constructed so as to lock itself and cock the firing mechanism, which is released by a lanyard.

Connected with the crank which operates the two smaller barrels is a shaft to which is attached two cams, each of which causes a carrier to move forward and backward. The cartridge rolls into the breech from the hopper, forcing the old shell out after it has been started by the outward motion of the carrier, and is forced into the breech by the return motion.

The three barrels can be fired at once or separately at the will of the gunner. The two half-pounder barrels are capable of being fired at the rate of 250 times a minute and the one-pounder 35 times a minute.

The one-pounder projectile is the same as is used in the Hotchkiss, Nordenfeld and other similar guns. Either solid shot or explosive shells may be used. It has an effective range of more than five miles. The gun complete weighs half a ton.

The other machine gun is of small caliber, and weighs only 54 pounds complete and ready for action. It is intended for field service, and can easily be carried by a squad of infantrymen. It is capable of firing a thousand shot a minute. There are four barrels, which shoot a 30-caliber cartridge, after the style of the Lebel. They are surrounded by an aluminum water-jacket. This is the first time this metal has been used in gun construction. The four barrels are operated by a single crank. Cartridges are fed into the barrels on an endless web belt.

Both guns will be taken to Europe soon, where they will be tested by the military authorities of one of the largest powers of the continent.

Long Distance Transmission of Steam.

At a recent meeting of the American Society of Mechanical Engineers, Mr. Eckley B. Cox described a method he had used in carrying steam a long distance. At a colliery they wished to carry steam to a water works about 4500 feet over a hill from the boiler plant. A trough was made by nailing the edges of two boards together, so that they formed a right angle. The trough was supported by two stakes driven in the ground, and crossing just beneath the trough. The pipe was laid in the trough resting in cast-iron plates, the pipes surrounded by mineral wool, and a similar inverted trough placed over the top. To

allow expansion, a bend was made to one side at the top of the bill, and then it was turned back to its original direction. A large receiver was introduced in the pipe at the pumps. This was made of three sheets of an old boiler and was 34 inches in diameter. This also served as a separator. As the elevation was 1800 feet above the sea, the cold was excessive in the winter time, but this arrangement has been in use since 1877, has cost nothing for maintenance, and has given no trouble. Mr. Cox believed that the secret in carrying steam long distances to an engine without causing a drop in the steam pressure was in the use of a receiver or reservoir.—Scientific American.

Smoke Prevention.

Probably people will keep on making a smoke until such time as it is made peculiarly a loss to them by means of penalties; but until then the majority of users of solid fuel will be loth to move in the matter. So long as the fuel bill is kept within a certain limit, people don't care; they argue that they are doing as well as their grandfathers did, and why should they want to make alterations, says Walter J. May.

At one large works in England, the whole of the smoke from a battery of boilers is washed and the ammonia, etc., taken out, the products obtained assisting in paying for the cost of the coal used, besides the working expenses, but the process is not largely adopted because our predecessors did not use it.

By pitting on two regular stokers on a battery of boilers the writer effected a net saving of £3 per fortnight over and above their wages on coal alone, or at the rate of £8 per annum; but because it did not matter about "a little smoke," the management would not continue the arrangement as it was "not the custom to employ firemen," and they still continue to put coal in the furnaces and to send it out of the top of the chimney unburnt. Clever, is it not?

In London the bakers are fined heavily for black smoke, and they do not have any, as a rule; but they find that while such smoke cannot be avoided where there is no penalty, where "40s. and costs" inflicted a few times more than covers the cost of a proper furnace. In some places the Town's Police Act is enforced, and if a chimney catches fire, the occupier of the house is fined. In such places, chimneys rarely catch fire; they are kept swept. But where the act is not enforced, at least 25 per cent of the chimneys in the district get burnt out. Why? Because there is no penalty.

It is no use whatever to advocate smoke abatement in any country until sharp penalties are imposed by an act of the Government and stringently enforced; and when this is done, people will at once arrange their furnaces and other fuel-consuming apparatus so that the fuel will be consumed, but not before.

A New Explosive.

At the Lavaux-sous-Aubonne powder manufactory, in France, some important experiments having been carried out with a view of testing the efficiency of a new explosive which has been invented by M. Raoul Pictet, the well known Swiss chemist. The discovery is the outcome of many years of inquiry into the composition and destructive effect of different kinds of explosives, and as all appeared more or less defective, M. Pictet set himself the task of inventing a new explosive which should be as perfect as possible, and has consequently prepared a compound which he calls "fulgurite." The principal claims for fulgurite are that it is quite smokeless, that the gases, though of greater volume than those of any other explosive, with the exception of fulminic cotton, are not deleterious, and that, while its use is absolutely safe, its destructive effects are quite as great as those of dynamite.—Invention.

THE GRIFFIN MILL.

A perfect pulverizer of all refractory substances by either the wet or dry process. It works better and at less expense than any other Mill, and is conceded to be the only perfect pulverizing Mill Manufactured.

Scientific Progress.

On Light.

The first lecture of a series which will no doubt prove to be most instructive was delivered by Lord Rayleigh, at the Royal Institution, says the London *Optician*. The subject, "Light, with special reference to the optical discoveries of Newton," was appropriately introduced by a discussion of methods of photometry. It was pointed out that the fundamental "inverse square" law on which the action of so many photometers is based has an obvious foundation quite independent of the particular theory under which the phenomena of light may be accounted for. But if there be, thus, a firm theoretical foundation for the law itself, the same thing cannot be said for its interpretations in the measurement of light-intensity by processes involving chemical change. Stress was put by the lecturer upon the recent elucidation of this unsuspected fact by Captain Abney, who, at one time, probably in common with all other English physicists who had given attention to the matter, professed his almost unqualified adhesion to that view which, as we now know, implies a failure to discriminate between the different ratios of thermal to chemical action proper to different intensities of absorbed light. Lord Rayleigh expressed the opinion that it would not be an unreasonable inference from Captain Abney's photographic discovery to assume a like departure from the true interpretation of feeble light-action in the retina of the eye. It is also possible by converse reasoning on Allard's investigation of interrupted vision to arrive at the same result. In this connection, by the way, a very interesting remark was made by Lord Rayleigh, that in playing tennis the approach of evening, and consequent deficiency of light for seeing, makes itself felt sooner than in almost any other way.

Our readers will be acquainted with the various propositions that have been advanced as to establishing a standard unit of light. Lord Rayleigh pointed out that, of course, the most desirable standard would be based upon the unit of energy. The difficulty which is felt relates to the question of refrangibility. We may mention that it was noted by us how enormously the visual effect of light, expressed as a definite quantity of work, varies according to the length or frequency of the waves. Remarking on this fact—the total distinctness of different colors in their relationship to the visual mechanism in the eye—attention was directed by the lecturer to the additional fact that, in making comparisons of colors, what is called equality in visual intensity with respect to different hues can be attained by optical adjustments which, under similar conditions, exhibit remarkable uniformity among themselves. He suggested, as probably worth studying in this connection, exact measurements of the automatic variations of the iris aperture. Of course there is no immediately obvious reason why the physiological action controlling the area of the pupil should not be just as uniformly responsive to change of lighting as is that retinal change by which the sense of vision is excited. There is perhaps more friction and inertia to be overcome in moving the iris muscles than in effecting any alteration in the condition of the retinal surface. And the pupil, regarded as something alterable by exposure to light, would probably exhibit Allard's relative unresponsiveness by pulsating light upon what may be called a very much rougher scale than that obtaining with respect to the retina itself. But still, no matter how coarse it may be, relatively speaking, the varying diameter of the iris affords a highly interesting measure of light. There are optical methods by which the diameter of the iris could be measured, although not so accurately that a scale of gradation at all approaching to the range of

that which vision affords could be marked out. And Lord Rayleigh supposes, if we understand rightly, that the possibility of regarding certain shades of distinct colors as visually of equal brightness depends in some way upon the photometric capacity of the iris muscles. At any rate the varying aperture of the iris is an important factor which must never be lost sight of in visual photometry.

Another point referred to by the lecturer is that, as exemplified by Schumann's researches, aerial absorptiveness makes itself felt much more in actinometry than in ordinary visual work. Turning from particular processes of measurement to the general laws involved in every optical phenomenon, it was observed that both reflection and refraction are governed by rules so firmly fixed upon a broad theoretical basis that any experiments to demonstrate their accuracy more fully than has hitherto been done might almost be regarded as useless. The same thing does not by any means hold good with regard to other fundamental laws, as, for instance, Ohm's law in electricity.

Mercurial Soap for Cholera.

According to the *American Architect*, two chemists of Hamburg, MM. Forster and Nijland, have published some studies on the cholera infection, from which it appears that soap is one of the best known sterilizers of water suspected of infection. For a long time after the cholera epidemic of last summer, the people of Hamburg were afraid even to bathe themselves with Elbe water, but MM. Forster and Nijland show that ordinary toilet soap, added at the rate of an ounce to about twelve quarts of water, will kill the cholera bacilli in ten minutes. This would be a large proportion of soap to use in a bath, but as most people, instead of dissolving soap in the bath water, apply it to the skin with a sponge, it is probable that the water actually brought in contact with the skin is generally soapy enough to be harmless. If, however, it is desired to obtain greater security, a soap containing a small quantity of corrosive sublimate may be used. Many "complexion washes" contain this drug, which is said to have a beneficial effect on the skin, however dangerous it may be internally, so that no hesitation need be felt in employing soaps medicated with it, and a very small quantity is sufficient. With a soap containing one per cent of corrosive sublimate, added at the rate of a quarter of an ounce of soap to sixty quarts of water, all the cholera bacilli will be killed in one minute, and half the dose will kill them all in ten minutes; while the sublimate alone is still more active, an ounce being sufficient to destroy, in five minutes, all the cholera microbes in about a million quarts of water.

Where Did the Tails Go?

The apostles of evolution have never satisfactorily accounted for the disappearance of tails among mankind. It is interesting, therefore, to read that Prof. Drummond thinks the end of the vertebral column, consisting of three, four and occasionally five vertebrae, called the coccyx, forms the real rudimentary tail. In the adult this is always concealed beneath the skin, but in the embryo, both in man and apes, in an early stage it is much longer than the limbs. What seems decisive as to its true nature, however, is that even in the embryo of man the muscles for wagging the tail still exist. In the grown up human being those muscles are represented by bands of fibrous tissue, but cases are known where the actual muscles persist through life. That a distinct external tail should not be still found in man may seem to refute the arguments of the evolutionists, but it would have been contrary to the theory of descent had he possessed a longer tail, for all the anthropoids most allied to man have long since

parted with theirs, so the absence of tails is more favorable to the idea of evolution than their presence would have been.

Electric Progress.

Steering by Telephone in a Fog.

For some time Mr. Charles A. Stevenson has been making experiments for locating the position of vessels at harbor entrances, which would be of service when, during certain states of the weather, other observations cannot be easily made. He proposes, according to the *London Pall Mall Gazette*, that a cable might be laid down in the sea, and, by changing the electric state of the cable, vessels passing near or over it might be able, by means of a detector on board, to discover that they were in its vicinity. Some experiments showed the method to be feasible, since the sea offers no insurmountable difficulty, and he has constructed two instruments which will act through 180 feet of water.

The first instrument is a coil of uninsulated copper wire rope dipping into the water at the bow of the boat and a similar water connection at the stern. If these are joined by a wire with a telephone on the circuit, it will be found that, even without an induction coil or other arrangement to magnify the effect, a very sensitive instrument is produced; and that, when the wires from bow to stern of the boat are at right angles, or nearly so, to a cable laid in the water at some distance from it, the sounds produced by a magneto-electric machine connected to one pole of the machine are audible in the telephone. If the water connections are equidistant from the cable, as they would be if the boat were immediately over the top of it, or lying broadside on, no sound is heard. The action takes place when the coils in the water are insulated. The cable also may be insulated or uninsulated. The action is similar with an induction coil, and will also act if the potential of the cable is charged and is then kept so. With the coils separated 10 feet (at the bow and stern of a small boat put down from the vessel), and an insulated wire 400 feet in length laid through a small lake of brackish water 15 feet deep, the alterations produced by the bobbins of a magneto-electric machine were perfectly distinct at the end of the lake, 340 feet away from the wire, and the limit of audibility could not be ascertained. Further trials will be necessary to determine the law of the falling off of the intensity of sound with the increase of the distance from the cable for a given fixed distance between the water connections, as well as to determine the law of increase intensity for any increase of distance between the bow and stern connections for a given fixed distance from the cable.

Mr. Stevenson's second instrument is a coil of insulated wire surrounding a core—that is, an electro-magnet with a telephone in the circuit of this coil. With this instrument the making and breaking of the current produced through a wire 200 feet in length could be detected through 60 feet of salt water. When sunk in water the sound seems just as loud. He is of opinion that the action of the instrument consists in the break, if broken sufficiently rapidly, inducing a current in the coil, which the core intensifies immensely. The sound in a Bell telephone with the instrument was almost deafening with 15 feet depth of water. This electro-magnet system of induction, in contradistinction to the parallel wire system, has no earth connection, being entirely insulated, and must, therefore, be a case of true induction through water.

Electric Light for the Piano.

A clever design has been brought out for enabling electric lights to be thrown on the musicboard of a piano, even when no street mains are available. The lamps project from the front of the piano, in the usual way, but the portable battery from which the current is derived, a switch, and the necessary electrical connections, are placed

behind the musicboard. This is done by making the musicboard slope at a more pronounced angle, but it does not otherwise interfere with the working of the piano. The whole of the front can be lifted out, including the battery end of the lamps, leaving the interior free for tuning, as usual. A lithanode battery is used, which, once in position, can be securely fastened with lock and key.

Electricity in the Perfumer's Laboratory.

The manufacturers of old and favorite brands of perfumery are just now greatly exercised by the accounts of a new development in Paris. It is stated that a perfumer in that city has recently suddenly acquired a remarkable reputation for the super-excellence of his wares, which exhibit a phenomenal charm and subtlety. What for a time perplexed his fellow perfumers, who were thus distanced in business competition, was the fact that although his sales were much greater than ever before, his purchases of essential oils were much less, both in regard to quantity and variety. The secret is now divulged. The enterprising perfumer had read that ozone was used for the purpose of mitigating the crudities of new wines and spirits, and tempering and softening their flavor, and he thought he would try its effect on perfumes. Fitting up his laboratory with the needful electrical appliances, he set to work and soon found that the odor of essential oils could be surprisingly modified by the action of ozone, and that by the skillful combination of spirits and essences, and their treatment with the ozonizer, he could vary their delicacy or power at will. If this discovery should prove to be trustworthy, a vast field is opened to the perfumer, who will now need but to lay in a stock of alcohol and bergamot to turn out essences of the widest range, from the stimulating fluid that is more pungent than the strongest aromatic vinegar, to the scented drops that intoxicate the senses like the morning air when the orange trees are white with bloom.

Electric Light as a Disinfectant.

Professor H. M. Ward's researches on the influence of light on bacteria have brought out some remarkable facts. Prof. Ward demonstrates conclusively that the naked arc light may be used in hospitals or railway cars most effectively as a disinfectant, by reason of the effect of its rays upon bacteria. He has allowed the various rays of the spectrum to fall on films of gelatine or agar containing spores of bacteria, and finds that whether the spectrum is got from sunlight or electric light, there is no perceptible action on the spores of bacteria by the infra-red, red, orange or yellow rays, while all the spores are injured by the rays of the blue and violet region. Broadly speaking, the injurious action begins at the blue end of the green, attains a maximum in the blue, and diminishes toward the ultra violet. With the electric light, quartz lenses and prisms had to be used in forming the spectrum, as the results with glass were feeble. The injurious influence of the blue rays extended far into the ultra violet. The intervention of a thin piece of glass resulted in cutting off a large proportion of effective rays.

Blocks of Carbon in Lungs.

The lungs of a polisher of electric light carbon terminals were exhibited by M. Lancereaux at a recent meeting of the French Academy of Medicine, and it was shown that the said organ had been transformed into veritable blocks of carbon. Up to the age of 36 the deceased had been a robust stonemason, but was then transferred to a workshop eight metres long by seven broad, where, with eight other men, he was engaged in polishing on stone mills carbons

for electric lighting. The shop was so badly ventilated that sometimes they could not distinguish each other through the stone dust and charcoal filling the atmosphere, and the result was apparent in M. Lancereaux's exhibit, which was a strong argument, if one was needed, for the better ventilation of workrooms and the use of the respirator.

Lamp for Musicians.

An ingenious little lamp has been devised for the use of musicians in an orchestra during a dark change in a theatrical or operatic performance. At the top of each music desk is a cylinder containing two 16-candle power incandescent lamps. The cylinder has a quarter-inch slit along its entire length, and when placed at a certain angle sheds light all over the page of music, while all around it is dark. This is said to be far more effective in every way than the ordinary shade.

Long-Distance Telephony in Spain.

An important long-distance telephone line is being constructed between Madrid and Barcelona, a distance of about 500 miles. The line will pass through Saragossa and is expected to be ready within three months.

Practical Information.

Origin of the Dollar Mark — Five Theories.

Below I give five theories of the origin of the dollar mark (\$), they being selected from about twenty seemingly plausible solutions:

1. That it is a combination of "U. S.," the initials of the United States.
2. That it is a modification of the figure 8, the dollar being formerly called a "piece of eight."
3. That it is derived from a representation of the pillars of Hercules, consisting of two needle-like towers or pillars connected with a scroll. The old Spanish coins marked with the pillar device were frequently referred to as "pillar dollars."
4. That it is a combination of "H. S.," the ancient Roman mark of unit money.
5. That it is a combination of P and S, from peso duro, signifying "hard dollar." In Spanish accounts peso is constructed by writing the S over the P, and placing it after the sum.

According to one writer the symbol of the dollar is a monogram of the letters "V," "S" and "J," the dollar being originally a "thaler," coined in the valley of Sankt Joachim, Bohemia, and known as a "Joachim's thaler," and the monogram the initials of the words, "Valley Sankt Joachim." A writer in giving his opinion of "Reason No. 3," as given above, says:

"The American symbol for dollar is taken from the Spanish dollar, and the origin of the sign, of course, must be looked for in associations of Spanish coins. On the reverse of the Spanish dollar is a representation of the pillars of Hercules, and around each pillar is a scroll with the inscription 'plus ultra.' This device in course of time has degenerated into the sign which at present stands for American as well as Spanish dollars, '\$.' The scroll around the pillars represents the two serpents sent by Jnno to destroy Hercules in his cradle in mythologic lore."—St. Louis Republic.

A Substitute for Linseed Oil.

The *London Engineer* gives the following patented method for preparing a composition oil, possessing the qualities of linseed oil, as a vehicle for paint. The composition consists of crude petroleum, 1 gallon; yellow beeswax, $\frac{1}{4}$ lb. to $\frac{1}{2}$ lb.; powdered resin, $\frac{1}{2}$ lb.; zinc sulphate, $\frac{1}{2}$ lb. to $\frac{1}{4}$ lb.; lead acetate, $\frac{1}{2}$ lb. to $\frac{1}{4}$ lb.; rubber, $\frac{1}{2}$ oz. to 1 oz.; linseed oil, $\frac{1}{2}$ pint to 1 pint. A still, similar to a large steam boiler, with a

dome and manhole, is employed. This still is provided with two sets of coiled tubing inside, one set being perforated for admission of steam. The crude petroleum is first placed in the still, and blown by direct steam for six or eight hours, till the lighter impurities have passed out to a suitable condenser. The lead acetate and zinc sulphate are then added to the petroleum. The contents of the still are heated by sending steam through the coil of closed tubing, till the solution has boiled for an hour. The beeswax, resin and rubber are then added, and the ingredients boiled together for about seven hours. The mixture is then allowed to cool, and the linseed oil added.

Aids to Longevity.

The philosopher may balance the advantages and disadvantages of long life, and may decide in favor of a short time of human existence. But it is clearly a prime part of the business of the physician to make life as long as possible, and as comfortable. There are two sorts of pressure which tend to shorten life—blood pressure within and atmospheric pressure without. This latter is a specially important factor in a humid climate like our own. In advancing age the circulation of the blood and lymph tends to become slow, and the enfeebled heart finds its embarrassments increased by this condition. Especially do the more vascular organs, such as the lungs, the liver and the kidneys, put skids on the wheels of the blood circulation. Plainly, then, an important condition of cardiac easement, and therefore of life prolongation, is the maintenance of an uncongested state of lung, liver and kidney. Thus are internal pressures relieved, and thus is cardiac energy conserved. Of almost equal importance, at any rate in Great Britain, is the question of atmospheric pressure and moisture to aged persons. Situations which are at once low-lying and damp give, of course, a maximum of atmospheric pressure. Such pressure weighs down at a single stroke body, mind and life. The difference to aged persons between living at the sea level and living 500 feet above it, between living in a moist atmosphere and living in a dry one, is sometimes quite incalculable. Not seldom life may be lengthened by five or even ten years by living in an atmosphere which is both light and dry. These physiological considerations are commended to the aged and to the physician of the aged. While physiological explorers are busy in the laboratory, clinicians must not imagine that new discoveries can be applied in practice without constant and intelligent effort on their part. Knowledge, like freedom, "filters slowly down," but there is no objection to a little artificial acceleration of the pace.—Hospital.

Light in Machine Shops.

An observing mechanic has just come to the conclusion that a ray of light can get so badly distorted in a machine shop that no dependence can be placed upon it. If a number of gas jets are used when lighting-up time arrives, the heat about every jet is enough to rarefy the air to such an extent as to form just the medium for bending the rays of light and to deceive every mechanic who may be trying to work up to the mark. If rarefied air is disturbing the rays of light to such an extent that "things are not what they seem," that a straight line appears to be curved a trifle, and everything in general slightly on the move, this observing mechanic can rest assured that something beside the rays of light need looking after. A defect that can be traced to this source would naturally take into account that every piece of machinery is undergoing a change in position wherever this rarefied air comes in contact with them. The man at the lathe is boring out tapered holes just from the effects of expansion due to the heat that is being absorbed by the lathe bed. A me-

chanic that is so fine in his work that ray-hending is a source of trouble should take note of a dozen other defects that are going on around him that are far more notable in this respect.—Boston of Commerce.

Origin of the Locomotive Whistle.

When locomotives were first built, and began to trundle their small loads up and down the newly and rudely constructed railways of England, the country roads were, for the most part, crossed at grade, and the engine driver had no way of giving warning of his approach except by blowing a tin horn. This horn, as may be imagined, was far from being a sufficient warning. One day, in the year 1833, a farmer of Thornton was crossing the railway track on one of the country roads with a great load of eggs and butter. Just as he came out upon the track a train approached. The engine man blew his tin horn lustily, but the farmer did not hear it. Eighty dozens of eggs and fifty pounds of butter were smashed into an indistinguishable, unpleasant mass, and mangled with the kindling wood to which the wagon was reduced. The railway company had to pay the farmer the value of his fifty pounds of butter, his 960 eggs, his horse and his wagon. It was regarded as a very serious matter, and straightway a director of the company, Ashlen Bagster by name, went to Atton Grange, where George Stephenson lived, to see if he could not invent something that would give a warning more likely to be heard. Stephenson went to work, and the next day had a contrivance which, when attached to the engine boiler, and the steam turned on, gave out a shrill, discordant sound. The railway directors, greatly delighted, ordered similar contrivances to be attached to all the locomotives, and from that day to this the voice of the locomotive whistle has never been silent.—Birmingham Daily Post.

A Lightning Calculator.

The new theater of Koster & Bial's, New York, is just now a point of interest to the mathematician.

M. Inaudi, of Paris, astonishes every one by his marvelous feats with figures. With his back to a large stage blackboard he reads off accurately long lists of figures given by the audience and written down by an assistant, the figures apparently becoming photographed on his brain and remembered without effort. When later he is called upon to repeat them, each figure is four different sums was correctly remembered and the problems solved, although M. Inaudi permitted a quarter of an hour to elapse after the writing of the figures on the blackboard before he read them off, devoting himself meanwhile to telling the day of the week on which any one in the audience was born, if they stated the year and day of the month. M. Inaudi explains this interesting feat by saying that one part of his brain goes ahead solving the several problems on the blackboard—the figures of which he has only heard announced once and had never seen—and another part of his queer gray matter attends strictly to the business of telling the members of the audience their birthdays!

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Ore; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Ore; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expeditives; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note. One of the methods given for the Assay of Copper is new and original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter. Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Miscellaneous.

The University of Oxford in England has the reputation of having been founded by King Alfred in 872.

Alum and plaster of Paris mixed with water and used in a liquid state form a hard composition and a useful cement.

Phillippe le Bel of France ordered that no tradesman's wife should wear a gown made of stuff costing more than twenty cents a yard.

In 1364 the pointed hoods worn by the ladies often reached four feet above the head, making the lady's face appear about the center of her body.

The longest train on record was that of Catherine de Medici on the occasion of her marriage. It was forty-eight yards, and borne by ten pairs of pages.

Gurit has collected figures which show that there is one death to every three thousand administrations of chloroform, while with ether there is only one fatal case in fourteen thousand. Ether is dangerous to the lungs; chloroform to the heart.

The total number of deaths in the United States in 1892 was about 900,000; the number of persons cremated that year, 503. As crematories have been in existence in the United States since 1881, these statistics indicate that the movement favoring the burning of the dead is not making much progress.

Commodore Decatur's first command was the Norfolk, in 1802; later he commanded the Enterprise. In 1804 he commanded the Intrepid in destroying the Philadelphia in the harbor of Tripoli. In September, 1804, he commanded the Constitution and later the Congress, and in 1809 commanded the Chesapeake. In 1810 he took command of the United States, frigate. In 1814 he commanded the President, frigate, which he had to surrender to four British vessels. In 1815 Decatur commanded a squadron in the Mediterranean, and humbled Algiers, Tunis and Tripoli, and returned home in 1816 to become a member of the Board of Navy Commissioners. He never went to sea again, and was killed in a duel March 22, 1820.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Spouters, etc., including, also, a full stock of Chemicals.
Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.
Agents of the Denver Fire Clay Co., and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.
JOHN TAYLOR & CO.

NEW METHOD

Of Roasting and Smelting different kinds of ores has been successfully demonstrated, and is now being introduced with unprecedented success. The slow and cumbersome methods heretofore employed will be discarded, and the cost of various ores in treatment or conversion into metal, greatly reduced. All the matte of the latter, which was heretofore sent to Germany, is now being refined in the United States.

All questions on metals, ores and their practical method of treatment readily and conclusively solved.

We are prepared to erect Reduction Plants, for same, and run them successfully for any length of time, to be agreed upon by contract.

Why experiment when you can have a certainty? Correspondence solicited.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with the shaft. SPECIAL CONSTRUCTION OF STEEL only one-eighth part the weight of the old pump. Works with 10 per cent less power. First outlay one-third less. Suitable to any under or downright shaft. Occupies less space in the shaft. Has been tested a year and proved to work satisfactorily in every respect. GLAND OF STUFFING-BOX TIGHTENED AND OIL LUBRICATED AUTOMATICALLY WHEN WORKING UNDER WATER. Works very much longer than any other pump under water.

IMPROVED SINKING DR BUCKET PUMP.

Bucket, clack and clack-seat changed under water. Bucket lasts six times as long as the old bucket, often saving expense of putting down another pump, especially in jack-head pumps, where bucket and clack cannot be changed under water. Special attention is called to the self-tightening stuffing-box and new bucket which obviates the expense and delay of frequently dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, Cal.

Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE COMPANY'S WORKS, 130 MAIN STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

— SAVED —

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILE IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW ORE CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ore. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 per cent; from East ledge, " " " a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,

E. L. BALLOU, Propr. Ballou Reduction Works.

THE PELTON WATER WHEEL!

EMBRACING IN ITS VARIATIONS OF CONSTRUCTION AND APPLICATION

THE PELTON SYSTEM OF POWER.

The most simple and efficient water power appliance for mining, electric or other service. Full and reliable information given regarding any proposed application upon receipt of the necessary data.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

RESUMPTION OF WORK.—Ledges: Work was commenced this week on the Matson mine in Butte Basin. There are four men at work there now and as soon as everything is in shape to see more they will be put to work. The work is in charge of H. Ferrel. S. T. Smallfield is in charge of the construction of a hoist to be used by horse power, with one bucket, while others of the employees are engaged in retimbering the old shaft. The present shaft is down about 90 feet, and about 50 feet from the surface a drift runs about 40 feet. On the same claim is a tunnel about 100 feet into the side hill from which rock milling \$5 per ton has been taken. The intention of the present management is to take out four or five hundred tons of rock and have it crushed in the Tripp mill, near Big Bar bridge. If the returns are satisfactory a steam hoist and a mill will be erected during the summer and work continued upon a large scale. Those in charge are certain of the success of the property, as the surface ground in that neighborhood was very rich in gold in early days. Mrs. J. Baptiste conducts a boarding-house on the property at which the men board.

The Argonaut people are sinking in that property as steadily as possible. The shaft is now down 125 feet, and is advancing as rapidly as possible in the hard rock in which they are sinking.

Workmen are engaged at the Kennedy in building an addition to the chlorinating furnace. The work of chlorinating has lagged somewhat of late on account of the small capacity of the furnace and it was found necessary to add about one-third to the capacity of the old one. In a few weeks the extra furnace room will be in operation and a few weeks later the chlorinating works will be up with the mill and can be kept there without taxing its capacity.

Nevada.

IN GOON SPIRITS.—Telegraph: Superintendent Stoddard returned from Sacramento last night, where he has been to attend a stockholders' meeting of the Centennial Mining Company. He informs us that the members of the company are well pleased and in good spirits over the outlook. The 650 level is especially promising, and the company have decided to put in an air compressor and Burleigh drills. With this accomplished, the development work can be pushed ahead with great rapidity, and in a short time hence we may expect to once more see the Centennial upon the list of dividenders as it was in former years.

A VERY GOOD SHOWING.—Union: Although two dividends of 15 cents a share have already been declared this month, Superintendent Mainhart says another will be declared by the Omaha and Lone Jack Company next Tuesday. Last month's run was the best in the history of the mine. The ore being crushed this month shows improvement over that of March, but it may be possible that the cleanup will not be quite as large on account of part of the mill being used on tributaries' rock. A double track will be laid shortly in the Lone Jack, when all the quartz will be hoisted through it instead of the Omaha shaft. The mine is equipped with good machinery and was the first in the district to have all its works lit up by electricity.

The Wisconsin has been leased by several practical miners, who have made such a success of their venture that they have over 30 men hired under them at \$3 per day. The last crushing of 160 loads amounted to nearly \$10,000, and this month's yield, with Southern's and Perrin's mills kept running, will likely exceed that gratifying sum. The ledge varies in size, but will average 18 inches. The principal work is being done in the 300 level, but the shaft is being sunk and drifts will be turned when a depth of 400 feet is attained. The ore in the shaft improves in quality right along and will get better as the country explored by depth becomes more settled.

There is every reason for the fortunate owners of the Electric (formerly known as the Green Mountain) mine to feel enthusiastic. Every assurance is afforded that it will develop into a big property. The ore in the shaft, at a depth of 400 feet, is excellent milling ore, which improves in quality the deeper the mine is worked. The ledge here is from 15 inches to two feet in size, and will doubtless mill \$35 a ton or over. While sinking is in progress the mine is also being opened up by drifts north and south in the 300 level, but not a pound of ore has been stope out. The coming week a station will be cut at the 400 level and drifts turned both ways on the course of the ledge. In another week the new ten-stamp mill, which is a model one in every respect, will be started up, and it is expected that it will continue in motion incessantly. There are 40 or 50 tons of good ore on the dump, and with all the backs in the 300 level to be worked and the 400 level opened up, a good force of men employed will be able to keep it running.

In the Original Empire, during the past week, drifting was commenced on the 2100 level north. Within two months it is expected the pay chute will be reached. Very good ore is being extracted in the 2000 level north; and, while the quartz in the south drift of this level is of fair quality, the main chute has not yet been encountered. It is expected to tap the ore chute in this drift which yielded so handsomely in the 1800 level almost any day.

The South Idaho claim is regarded as very promising. The vein is a parallel one to its famous neighbor and is just the same character of ore. On Friday some ore was taken out

which showed considerable gold, but it is evident that before the real value of the mine can be known, greater depth is necessary.

The Orleans is holding its own in good shape. Ore is being stope in the north and south drifts of the 250 level and sinking is also progressing. The mine is practically paying its way now at a superficial depth, and for it to yield dividends all that is necessary is for the mine to have greater depth and be opened up. The new mill has not yet been commenced, but will be shortly. The ore averages \$30 per ton.

A fair test crushing of ore from the Granite Hill mine has never been made, but in about two weeks Supt. Waggoner expects to have a crushing which will determine the value of the ore. It is promising in appearance and will doubtless mill well. The drifts are being run, and preparations are being made for sinking. Twenty men are employed.

Supt. Bennalack is feeling in better spirits over the prospects of the Central North Star. He informs the writer that the ore is 50 per cent better than at the last report, and the quartz being saved will mill \$25 per ton. The ledge is 18 inches in size. Sinking will be continued for an indefinite time.

Supt. Coffin informs the writer that stock in the Kate Hayes mine is being rapidly taken, and that some time the coming month a plant will be placed on the mine so that work can be commenced.

Polkinghorn & Co., the lessees, are pushing work as fast as possible at the Crown Point. The principal work is being done in the 200-foot level. The ledge is seven feet in size and pitches to the south, contrary to that in the old workings. It is expected, when sufficient depth is attained, that the ledges will make into a valuable pay chute. The ore from the Crown Point contains much sulphurets, and has to be worked by the smelting process. It assays \$51.50 to the ton.

The prediction made some time ago, that the Osborn Hill when developed would be a good mine, is coming true. It is the largest of what might be termed the young mines, by reason of the fact that it was not worked to any extent when work ceased on it years ago, in Grass Valley mining district. Work is being done in the 400 north drift, 500 north and south and 600 north and south. About the end of the coming week, sinking the shaft will be resumed. The ore of the Osborn Hill will average \$36 per ton, and when the new mill is erected ought to prove a bonanza.

Discussing of other adjacent mines the Union says of the W. Y. O. D.: Although no dividends have been declared of late by this mine, it has more than paid expenses. The 600, 700, 800, 1000 and 1100 drifts are being worked right along and the sinking of the shaft is also in progress. In a short time the 1200 station will be cut and drifts run on either side. Air compressors and power drills will be put in the mine at once, so developments can be hastened.

Two weeks ago Superintendent Dalmaine started to erect machinery on the Normandy mine. It was all in place in eight days, and the shaft has been cleaned out to within a few feet of the bottom. The shaft was found to be badly caved and even as expensive to repair it as to sink a new shaft. The Normandy was worked only to a depth of 50 feet, but it yielded many thousands of dollars as far as worked.

Pushing the main drift and raising to strike the ledge is what is being done at the North Banner. Almost every day now the good news is expected that the pay chute has been uncovered. The North Banner has paid a number of dividends and by systematically working it more dividends ought to follow. A company with ample means owns the property and no expense will be spared to open it up.

At the St. John mine no new developments have taken place of late. The 500 drifts are being run and a crosscut in the 300 level. The ledge is large, but the main pay chute has not yet been discovered. It is expected to strike it any time, however. With such a large ledge when pay ore is struck the St. John will be a big property.

The Centennial mine, which in the early days yielded so richly, is making good progress. Drifting north and south on the 650 level is being pushed. The north drift especially is looking remarkably well. At a meeting of the stockholders held in Sacramento during the past week it was determined to develop the mine vigorously, and, to better accomplish the work, men have been put on eight-hour shifts. The company has decided to erect an air compressor and introduce Burleigh drills, and a new 50-horse power boiler has been contracted for.

ENCOURAGING REPORTS.—Nevada City Herald: M. D. Cooley is making good headway in his mine at Quartz Flat, near Washington.

Cole & Williamson are also getting along nicely, and will have a big mine some day. The Centennial Company will resume work on their mine up the Washington Ridge in a few weeks.

The Blue Jay mine, near Maybert, is reported looking splendid.

The big flow of water in the Yuba mine has been overcome, and sinking is progressing rapidly.

San Bernardino.

GLITTERING GOLD.—San Bernardino Index: On Salt creek, four miles east of Elsinore, is a six-foot lead of free-milling ore and sulphurets, with the contact vein between slate and granite. The lead runs in a northwesterly and southeasterly direction. There are a number of locations on it, and five of them are being worked and are showing up well. Returns from assays made of this ore gave \$3 to \$1000. This ledge has been known for many years; but as the cap rock only assayed \$3 in gold, no one had the nerve to open it up. There is not a doubt but that the parties now working there have made a very rich strike. This contact vein has been traced for 18 miles, and runs in

the direction of the place where Chas. Briggs made his big strike, about six miles south of Winchester. By following the contact in a northwesterly direction, it leads past some of the rich strikes of the Gavilan district and on to the old tin mine itself. There is talk of organizing a party to prospect along the contact systematically as far as the desert.

Sierra.

BAD MANAGEMENT ALLEGED.—Downieville Mountain Messenger: We learn that there was an attachment levied on the Mount Moriah mine, at American Hill, this week. Who the attaching parties are and the amount attached for we do not know. This mine has only been running for a little while and the failure is, presumably, the result of bad management, as the mine is known to be rich. Bad management is, and always has been, the bane of this county. Many good mines have been ruined by mismanagement and every one so ruined helps to give the county a blacker name and keep capital away. It should be made a penal offense for a man who knows absolutely nothing about mining to undertake the management of a piece of property.

Siskiyou.

Notas.—Yreka Journal: Preparations are being made to commence work on the Schroeder quartz mine at Deadwood, as the snow is rapidly disappearing to permit hauling of supplies and getting around at the mine, where there are still about three feet of snow. Teamsters will commence hauling wood this week for the summer supply in running the steam engine, and as the road improves, there will be about 20 tons of new machinery and stamps to be taken to the mine, which indicates that the owner has a big thing in the way of valuable gold quartz.

The Cherry Creek, Deadwood Creek, McAdams Creek and Greenhorn Creek miners are all doing a rushing business in ground sluicing, with an abundance of water, which will last a long time, on account of the great amount of snow on the mountain summits, with the ground thoroughly soaked from the extraordinary quantity of rain during the past winter. After the supply gets too light for ground sluicing, there will be sufficient water for a long time to continue washing up the bedrock gravel in the sluice boxes, with good success.

All the hydraulic claims along the banks of of Klamath river for nearly 60 miles, from Seiad and vicinity down to the triangular corner of Siskiyou county bordering on Trinity and Humboldt counties, are being worked energetically with good success. The banks along the river in that section are rich with gold, and the various creeks furnish an abundance of water with heavy fall for operating immense giants in mowing down the steep banks.

The Greenhorn blue-gravel mine, about a mile south of Yreka, is paying exceedingly well at present, about half an ounce a day to the man, with 21 hands employed. Three drifts have been run from the hoisting and pump shaft, and the gold taken out is mostly found on bedrock, of coarse quality, similar to river dust. There is a good supply of water for washing, which is likely to last until very late in the season, if not all summer.

Thos. Ewing, a San Francisco mining capitalist, has secured the interest of Gonzales in the Boyle quartz mine on Humboldt creek, and intends working the same on an extensive scale in company with Mr. Boyle. He has sent here from below a dozen good miners, who left Yreka on Monday last with a wagon load of supplies to commence operations on an extensive scale, with the expectation of taking out considerable gold dust this season.

Newton Lamb has commenced preparations for opening up his placer claim on Greenhorn creek above the blue-gravel mine of Tim Austin & Co., and before long will be engaged in sinking a shaft to bedrock. He intends putting up first-class hoisting and pumping machinery, in order to work the mine with profitable success. The success gained by Austin & Co. and Lamb will no doubt cause the sinking of shafts in various other sections of the Yreka basin.

Trinity.

THE SILVER GRAY SOLD.—Journal: A party of mining men, consisting of B. B. Deming and Mack Weber of Oakland and G. E. Evans of Auburn, arrived on the 8th inst. and put in several days in examining mines on Canon Creek. They are the gentlemen interested in the bond on the Silver Gray, which mine we understand is sold to them, the first payment to be made this month. The mine has been prospected for the past three months under the supervision of Frank Adams and shows up well. The company intend putting a mill on the mine at once, and will work men enough to keep the mill and mine running in good shape. From all indications times around Dedrick will be better this summer than for two years past.

THE LA GRANGE DITCH.—The water is now running through the La Grange Hydraulic Mining Company's ditch to the mine, with the exception of about three miles at the head, where the snow is very deep and there are some slides not yet cleared out. The water was turned through the pipe lines last Monday. The pipes are perfectly tight and there is no leakage. At present about 800 inches of water is delivered at the mine. In two or three days the Coal Creek water will be turned in, increasing the supply by three or four hundred inches. The ditch is in splendid shape. The mine now has a better water supply than ever before.

NEVADA.

Washoe District.

James G. Rule returned to the Comstock yesterday, says the *Enterprise* of the 14th, and expects to remain on the lode until his contract is completed. He is still confident of

developing ore on the 1000 level of the Consolidated California & Virginia in the time specified.

SCOAPION.—The east crosscut from the joint north drift on the 900 level from the Union shaft, started at a point 283 feet south of the station, was advanced 17 feet, making the total length 75 feet; face in porphyry and clay with seams of quartz.

SIERRA NEVADA.—The south lateral drift from the intermediate tunnel has been advanced 30 feet; total length, 603 feet; face in hard porphyry.

The joint east crosscut near north line from the north drift, 1520 feet west of the shaft, 900 level, has been advanced 21 feet; total length, 233 feet; face in clay and porphyry.

UNION SHAFT.—The joint east crosscut near the north line from the north drift, 1520 feet west of the shaft, on the 900 level, has been advanced 21 feet; total length, 223 feet; face in clay and porphyry.

SAVAGE.—On the 1050 level the north drift started in the east drift, at a point 85 feet south of the shaft, was advanced 17 feet; total length, 53 feet; face in quartz giving low assays. Have resumed work in the north drift from the station and advanced same 30 feet. The west crosscut from the southeast drift, started at a point 225 feet from the shaft, was advanced 11 feet; total length, 41 feet; face in quartz and porphyry. The south drift was advanced 10 feet, making the total length 155 feet from the shaft. On the 1100 level the north drift from the shaft was advanced 12 feet; total length, 147 feet; face in quartz and porphyry. On the 12th floor they are extracting some pay ore.

CHOLLAR.—The north drift, 100 level, is now out 117 feet; the face is in hard porphyry with streaks of low-grade quartz through it.

The west crosscut on this level, 300 feet south of the north line, was extended 23 feet; total length, 100 feet; face in a mixture of porphyry and quartz of low assay value.

POROSI.—The south drift on the 450 level has been advanced 24 feet; total length, 324 feet; face in porphyry and clay with a streak of good ore from 3 to 4 inches wide running through it. The south drift, 50 feet above the 450 level, is out 55 feet; face in porphy and low-grade quartz.

WARD COMBINATION SHAFT.—The west drift from the 820 level, Ward shaft, is out 725 feet from the shaft; face in clay and porphyry.

BULLION.—The west drift from the station, 820 level, Ward shaft, is out 725 feet; face in clay and porphyry.

BALCHAS.—On the 800 level the north drift has been cleaned out and retimbered a distance of 30 feet, making its total length 335 feet from the shaft. During the week 25 tons of fair-grade ore were extracted and hoisted to the surface.

CROWN POINT.—The south drift from the top of the 700 level raise on the 600 level has been extended 14 feet since last report, and is now out 48 feet. The face continues in porphyry. The south drift on the 7th floor of the 700-level raise is out 35 feet; advanced 18 feet. The face is in quartz, about the same character and value as last week. Have stopped the north drift on the 700 level and started a south drift from the station on the 500 level. The drift is out 13 feet, the face being in a mixture of porphyry and low-grade quartz.

JUSTICE.—The south drift from the winze sunk from the Blaine tunnel has been extended 15 feet since last report; total length, 61 feet. The face shows a width of three to four feet of fair-grade milling ore.

Sao. BALCHAS.—The north drift on the 1150 level, from the top of the 1200 level raise, has been extended 10 feet during the past week; total length, 59 feet; face in a mixture of porphyry and low-grade quartz. We continue to save a few tons of fair-grade ore per week from the south raise on the 1150 level.

CON. CAL & VA.—On the 1650 level the drift running north from the end of the crosscut run east from the drift run north from the east crosscut No. 1 from the north drift from the winze—down 52 feet—has been extended during the week 30 feet; total length 126 feet; continuing in porphyry, clay and quartz of low assay value.

In our workings in the vicinity of the winze, down 20 feet, we have extracted 16 carloads of ore—about 15 tons—assaying \$26.80 per ton.

1000 level (the Rule drift): The drift running south, from the upraise, 50 feet up at a point 353 feet south from the shaft station has been extended 30 feet; total length 65 feet; continuing in porphyry showing clay separations. The drift running north from the west crosscut No. 1, 527 feet south from the shaft station, has been extended 12 feet; total length 32 feet; in porphyry with streaks of quartz.

An east crosscut (No. 4) started at a point 477 feet south from the shaft station has been advanced 34 feet in a porphyry formation.

UNION MINE.—900 level—The Union Con. and Sierra Nevada joint east crosscut near the north line of the Union mine, running from the joint north drift which was run from the joint west drift, at a point 1520 feet west of shaft, has been extended during the week 21 feet; total length 233 feet; face in clay and porphyry.

MEXICAN.—1465 level—The upraise started near the mouth of the crosscut run west from the drift run south from the top of the upraise which was carried up 45 feet above the sill floor of this level, at a point 40 feet from the main north drift and 100 feet north from the south line of the mine, has been carried up during the week 8 feet; total height 66 feet; continuing in a very hard porphyry formation.

A joint work with the Ophir Company, we have been making repairs to the incline shaft

which extends downward from 1465 level station of the Ophir shaft.

OPHIR.—1465 level.—The drift run south from the crosscut run west from the main north drift, at a point 219 feet in from the mouth of the crosscut, has been extended during the week 19 feet; total length 25 feet; continuing in porphyry showing lines of quartz.

Have continued (jointly with the Mexican Company) the work of making repairs to the incline shaft which descends downward from the 1465 level station of the main shaft.

Central Tunnel.—The north drift from the main west drift has been reopened and repaired during the week 81 feet; total length reopened 277 feet. The face of this drift is within a short distance of the Mexican shaft.

ANDES.—420 level.—West crosscut No. 3 discontinued; face in hard rock. Have been timbering main north lateral drift. In West crosscut No. 1 from main north lateral drift we are chambering out for an upraise.

BEST & BELCHER.—On the 900 level during the past week the main north drift has been cleaned and repaired a distance of 160 feet.

GOULD & CUREY.—On the 200 level west crosscut No. 5, started from the northwest drift 432 feet from the main west drift, has been extended 16 feet; total length 1010 feet; face in hard porphyry.

HALE & NORCROSE.—900 level.—Advanced the south drift 12 feet; total length 182 feet; face in porphyry.

1100 level.—Advanced the south drift 14 feet; total length 181 feet; face in porphyry.

KENTUCK.—On the 1100 level in extending the south drift from the top of No. 1 upraise we have extracted a few tons of fair-grade ore. On the 1200 level the south drift from the Jacket incline is now in 44 feet and continues in low-grade gold ore.

OCCIDENTAL.—From the west ledge above the 400 level we have extracted about eight tons of ore of the average assay value of \$42 per ton.

WEST CON. VA. & CAL.—During the past week the west crosscut on the 1100 level run from a point 320 feet north of the shaft station has been extended 27 feet in hard quartzite, and is now in a total distance of 679 feet. The flow of water from the face has somewhat increased since the last report. The material in the face of the crosscut is unchanged.

ARIZONA.

SOUNDS BIG.—The *Mesa Free Press* says: The Mammoth mine, at Goldfield, took out 70 pounds of gold in an eight-hours' run last week. There is not a mine in America that can beat it. The rock that is being blasted out of the bed of the wash near the mill runs as high as \$20 per ton. There is said to be over one and one-half million of dollars in sight within a few yards of the mill. It is the richest mine in the United States to-day, yet there are many more up there just as rich awaiting development.

ANOTHER BIG STORY.—Mohave *Miner*: From the big bend of the Colorado comes the report of immense gold discoveries. The Smuggler mine, at Rustler, has a shaft six feet in depth and it is estimated that there is fully \$1000 in sight for every foot in depth. Some of the ore has been brought to town and is on exhibition at Harley Fay's. The rock is a glittering mass of gold. Many extensions have been located and it now looks as though the rush in there from the outside would be greater than that caused by the White Hills boom of two years ago. A few days since a young Mormon lad, who had been packing water to the camp, lost his burros and while searching for them he stumbled onto a reef of white, talcy-looking rock that appeared to be mineral bearing. He took some of the stuff to camp with him and had it tested in a horn spoon. The result was surprising. From a small piece of rock nearly a teaspoonful of gold was obtained. The metal was very heavy and appeared to be almost pure gold. The young man and John A. Reeves have located the ledge and the other day they made a crosscut on it, exposing eight feet of ore. The whole eight feet was sampled and gave returns of from \$100 to \$1000 in free gold to the ton. The owners say that the rock can be ground to a powder in the hand and then the gangue can be blown away, leaving in the palm bright, virgin gold. Mr. Reeves, who is an old miner, says he has never seen a better surface showing. In every gulch gold can be found in the gravel. These important gold finds again bring forth the story of the thousands of dollars taken from that region in the spring of 1869 by a number of adventurous prospectors.

COLORADO.

IN THE SAN JUAN COUNTRY.—Silverton *Miner*: The Nevada has had ore all winter and lately have struck additional hodies in the lower workings. Shipping will be begun shortly.

The Lackawana mine on Kendall mountain, lately sold to Chas. Fieber, is being worked by eight men and is producing valuable ore. The assays are light.

The Aspen mine, which for many years has been a constant shipper, is keeping up her reputation. She is working 25 men and is shipping about a carload of ore a week.

E. G. Stoiber, of the Silver Lake, will be in by the 15th of this month. Mr. Stoiber has been absent all winter traveling in Europe and Africa. In the meantime his valuable mine has not been idle. Over a hundred men are at present employed, and 1000 tons of concentrate await shipment by the packers as soon as the animals come in.

The Enterprise group of mines on Sultan mountain have been leased and bonded by W. H. Johns & Co., and will be worked the coming season by a force of about 15 men. The company have leased the Reed mill, where they

will concentrate the ore. A trial mill run was given a few days ago to a couple of cars, which exceeded the expectations of the owners.

IDAHO.

FREE-MILLING GOLD ORE.—GRANGEVILLE, Idaho: Late last fall considerable rich free-milling gold ore was found in the Dixie district, about 30 miles south of Elk City, in the Bitter Root mountains. Only a very little work had been done on the three or four claims, yet the veins appeared to be well defined. E. V. Johnstone, a prospector, is in from the Dixie district and reports a big strike. The drift on the Sampson was advanced 20 feet, and uncovered a 34-foot vein of free-milling ore which will average across the vein over \$100 per ton in gold. On the Dilliner claim the 104-foot drift was driven 18 feet and cut a solid vein nearly two feet wide which averages \$185 per ton in gold. The report of the strike had preceded Mr. Johnstone to Elk City and the people of that city were very much excited and have no doubt stamped into Dixie district. Mr. Johnstone came out to Grangeville for supplies and will go back just as soon as the trail is free of snow, he having made the trip part way on snowshoes. The trail will be open for pack animals in another month. Over \$60,000 have been taken out of the placers in Dixie district, which are said to be wonderfully rich.

MONTANA.

Cor. Butte Miner: The snow is commencing to melt in the mountains, and the placer miners on Cedar, Trout and Quartz creeks are preparing to commence work. The coming season promises to be the most prosperous for a number of years. Several enterprises which were commenced last year will be in a position this year to work large amounts of gravel and will add considerably to the gold yield of the year for this section.

The Missoula Placer Company, which has two large flumes and a giant hydraulic plant at the mouth of Quartz creek, is working ten men and will probably increase the force in a few weeks. It will commence sluicing in a few days.

Ensign & Co., five miles above, are working, and will probably take out considerable money this summer.

Ancker & Walters have a 40-inch flume, 800 feet in length. They struck bedrock late last season and found good pay. They have a 16-foot bank of gravel.

Monteleus Bros. have 400 feet of flume, the end of which is within about two feet of bedrock. They will commence work immediately. Silverman & Newman have a 40-inch flume on the old Bisskin diggings. They have whipsawed 5000 feet of lumber during the winter and are prepared to handle a great deal of ground this season.

West & Stern are drifting on the creek above and have made good pay all winter. They will probably continue all summer. About three weeks ago they found a \$40 nugget.

There are a number of prospectors already looking for placers, and it is thought that several new flume enterprises will be inaugurated this season. The country yielded a great deal of gold when mined in a primitive way by the early miners, but with the building of large bedrock flumes and the introduction of hydraulics there has come a new era to this section which promises to make it a great placer mining district.

The first of these large fluming propositions to be successfully inaugurated was that of the La Casse brothers on Cedar creek. For the last two years this has yielded very handsome profits and is making the owners rich. Last summer's yield from this claim was about \$18,000. Each year they are able to handle a larger amount of ground.

There are large bodies of gravel in many of the gulches. These need only the application of scientific methods to make them immensely profitable. There is a great deal of gold quartz in the country. This is also attracting attention and several mining enterprises of this description have already been inaugurated.

On Nine Mile creek the Nine Mile Mining Company has been forced to a temporary suspension owing to the large amount of surface water from the melting snows. The mine is looking better than at any time during its previous history. The recent cleanups from their 20-stamp mill have been very satisfactory.

A recent strike was made on the property of the Sam Martly Mining Company, which adjoins the Nine Mile claim. A five-foot body of high-grade free-milling ore was struck. Arrangements will probably be made to work it in the 20-stamp mill of the Nine Mile Company.

OUT OF WORK.—Butte *Inter-Mountain*, April 14: On account of the Great Northern strike, 700 men in the employ of the Boston & Montana are thrown out of work, and a like number may be similarly affected at Great Falls if the strike continues much longer.

The Butte & Boston will not be affected to a great extent, as the matter now going to Great Falls will be shipped East. The Anaconda Co. will soon be obliged to get its supplies of fuel and lumber via the Montana Union if the strike is prolonged. Aside from these difficulties, everything is in operation as usual.

THE EMPIRE SOLD.—J. Henry Longmaid was in Butte on Friday. He said he had just sold out the Empire mine, near Helena, for \$15,000 cash. With the property goes five lawsuits, one being for \$100,000. Sam Ward and others are the purchasers. Mr. Longmaid understood that the Pigan Mining Co. would work the Empire, they having adjoining interests. Relative to the Penobscot, which Mr. Longmaid owns exclusively, he says it is yielding a profit of about \$4000 per month. On the 2d inst. the mill cleanup was \$4200 and on the 7th, \$2800, making a product of \$7000 in ten days. He reports having struck a chnt of ore recently that

mille \$20 to the ton on the plates. This ore body has been proved 50x40 feet, and he has every reason to expect that when it is fully opened up he will have 200x600 cubic feet of this class of ore hocked out.

UTAH.

Park City Record: On the 5th a clean-up was made at the Mareac mill and refinery and the following shipment made to the Omaha and Grant Smelting Company: Refinery cleanings, lots 1 and 2, containing 68 sacks; assay value, 3026.95 ounces of silver. Residue, lots 16 to 22; assay value, 4722.50 ounces of silver and 106.162 ounces of gold, the latter valued at \$2194.37. Lead carbonates, lots 1 and 2; assay value, 4310.24 ounces of silver. Base sulphides, lot 1; assay value, 8511.63 ounces of silver, making a grand total of 22,371.29 ounces of silver and \$2194.37 in gold.

BRITISH COLUMBIA.

SUBAQUEOUS MINING.—Nelson *Miner*: Subaqueous mining along the Fraser and Thompson rivers has been prosecuted with a vigor which has not before been shown in British Columbia. The Finch Mining Company has commenced operations at the junction of the Thompson with the Fraser river. The capital in this company is all from Pittsburg. The Vancouver company, known as the Kanaka Bar Gold Dredging Company Limited, has also commenced operations.

HYDRAULIC WORK IN CARIBOO.—John B. Hobson, the consulting engineer of the Horsey and Cariboo Hydraulic Mining Companies, has returned to Cariboo from California. He has with him a staff of millwrights and will proceed with the erection of a sawmill and the getting out of the necessary cut for the operation of his companies. He reports the steel pipe to be already on the ground, and expects to proceed with laying the same and the several miles of necessary ditching as soon as the snow is off the ground and the season opens.

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market St., S. F.

518,091.—SAFETY GAS COCK.—Clot & Malwald, S. F.
518,053.—LUBRICATOR.—J. Q. Finch, S. F.
518,140.—CAR COUPLING.—S. J. Ford, Placerville, Cal.
518,061.—SPRING REGULATOR.—H. B. Gale, S. F.
517,940.—CAR COUPLING.—C. W. Hinton, Los Angeles, Cal.

517,909.—WOODEN PIPE.—E. T. Wheeler, Los Angeles, Cal.
517,943.—TIME INDICATOR.—C. Worth, Los Angeles, Cal.
NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

LUBRICATOR.—John Q. Finch, San Francisco. No. 518,053. Dated April 10, 1894. This invention relates to improvements in lubricating devices for machinery. The object is to provide an automatic feeding cup which will supply a thin film of oil to the surface to be lubricated, while the parts are in motion, but which will cease to feed whenever the parts are quiescent, thus economizing the amount of oil which is used, and allowing no waste, drip, or leakage, while the machinery is idle. It consists of a cup adapted to be applied to any moving part, and having a central cone extending up into its interior, and in line with a passage which leads down to the surface to be lubricated. Within this cone is a metallic conductor, impervious to oil, which is bent so that one end dips into the oil within the cup, the conductor rising over the top of the cone which is above the surface of the oil, and thence passing down into contact with the surface to be lubricated. A slight tremulous motion of the conductor is the result, and this motion seems to act in conjunction with capillary attraction to raise the lubricant and cause it to pass down to the surface, but as soon as the machinery is quiet, and there is no motion of the conductor, the oil ceases to feed.

CAN HEADING MACHINE.—Mathias Jensen, Astoria, Or. No. 518,105. Dated April 10, 1894. This invention relates to an apparatus for the heading of cans. It consists of a can-head holder having a semicircular recess into which can heads are received, a semicircular hinged guide adapted to hold the can head to close and remain closed by the gravitation, a means for rocking the can-head holder to and from the can body, and a mechanism for delivering the cans successively into a holder in such position that the movement of the can-head holder will apply the head to the end of the can. It will be manifest that by duplicating the can-head holder and mechanism, that heads can be put upon the opposite ends of the can body simultaneously, and each can body is then delivered into a discharge chute as soon as the heads are applied, while a new one is received in readiness for the operation. The invention comprises many details of mechanical construction which cannot be well explained without engravings.

SAFETY GAS COCK.—George W. Cini and Gustav Malwald, San Francisco. No. 518,091. Dated

April 10, 1894. This invention relates to a safety attachment for gas burners. The object is to provide an automatically operating safety cock by which the flow of gas will be cut off if the main cock be accidentally opened. The supplemental cock has notches upon opposite sides, with a pawl which is adapted to engage one of the notches to retain the cock in an open position, and a lever is fulcrumed near the upper end of the burner having its lower end provided with a pawl to engage the other notch. The upper end extends across the burner tip to form an expandable bar, extending thence down upon the opposite side where it is affixed, so that the expansion of the transverse bar moves the lever about its fulcrum and causes it to engage the notch in the cock as long as the heat continues. If the gas should be put out, as soon as the bar became cool, the action of the lever would be to disengage the pawl and a weighted arm connected with the cock would immediately act, as soon as the disengagement takes place, to close the cock, thus automatically shutting off the flow of the gas, even though the main cock may be open.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower engine and 46-horsepower boiler, with Ore-crusher and other machinery, Mill Scales, Assaying outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

THE GOLD AND SILVER EXTRACTION COMPANY, OF AMERICA.

LIMITED.

TRADE MARK.

MacArthur-Forrest Cyanide Process.

CAPITAL, £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MacARTHUR-FORREST CYANIDE (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.

Advisory Board in the United States: Thomas W. Goad, Mgr.; Hugh Butler, Att'y; John F. Bell; P. G. George Goad.

OFFICE:

McPHEE Building, DENVER, COLORADO.
Agency and Experimental Plant, Mechanical Arts Building, Midwinter Fair, San Francisco, Cal.

PIONEER REDUCTION CO., NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract, or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ores or concentrates.

Address all communications to

PIONEER REDUCTION COMPANY, NEVADA CITY, CALIF.

THE ORIENTAL GAS ENGINE

IS THE BEST, because it combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

M. A. GRAHAM, Inventor and Manufacturer,

105 BEALE STREET, SAN FRANCISCO.

LOANS AND MINES.

Loans negotiated on first-class securities. Mines and mining prospects of guaranteed value sold on working bonds. C. H. DWINELLE, Grand Hotel, San Francisco, Cal.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner..... \$550, f. o. b.
 " " " Improved Belt Frue Vanner..... 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

SAN JACINTO ESTATE, LIMITED,
 Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CAJALCO, Dec. 18, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

The Case Automatic Engine.

The cuts herewith presented illustrate the Case Automatic High Speed Engine for small powers. Parke & Lacy are the San Francisco agents. Fig. 1 exhibits the engine equipped with a throttle governor as in the other forms of this engine.

The cut-off valve is of the plug type, perfectly balanced, and made with a slight taper so that it can always be kept tight. Its only duty is to define the point of cut-off, the admission, release and exhaust closure being controlled by the rocking of the cylinder which forms a valve action.

The lower half of the case forms a reservoir for oil and

that in the other, and very smooth running is thus obtained.

It is claimed that this engine runs at a higher speed than possible for a single cylinder engine of equivalent power, and the duplex feature in connection with light running parts marks the farthest advance in modern high-speed engine development.

A Drilling Contest.

On "Miners' Day," May 22d, at the Midwinter Fair, there will be a series of drilling contests, under the auspices of the Miners' Association executive committee, free to any competitor on the Pacific coast. It is thought that

counties. Of course, one part of the commonwealth can not be hurt without indirect injury to all, but if the dry summer of '94 will direct more attention to the mineral wealth of the State it will be a blessing in disguise.

A Great Advantage.

California's greatest present advantage is in the possession of its gold mines. The occupation of gold mining is the one industry to-day that is a prosperous one, and with the broadest horizon, because the product is steadily increasing in purchasing power.

While regrettable in the abstract, yet it is a patent fact that the value of a gold dollar was never greater than to-

FIG. 1.

FIG. 2.

THE CASE AUTOMATIC ENGINE.

water, into which the crank-pin dips at each revolution.

The lubricant is conveyed to the bearings at every stroke automatically by pockets in the crank-discs; after the oil has done its work on the bearings it returns to the case again by gravitation. Any excess, which would naturally work out on the shaft, is thrown off by centrifugal action, from ring wipers, and returned by a separate passage to the case; thus the same lubricant is used over and over again. The oil and water find their way through small openings to a settling chamber below the reservoir, and being away from the churning action of the crank, the oil separates from the water and returns to the upper case. A stand-pipe is connected with the bottom of the settling chamber, and consequently the overflow itself is always water. The cylinder is lubricated by an efficient sight feed oiler, furnished with each engine, to be connected to the steam pipe.

Fig. 2 shows the double engine made by combining two cylinders in one frame. The crank is a solid steel forging with pins set opposite.

The throw of metal in one cylinder counterbalances

if mining superintendents have competitive local contests they can send good drillers to compete. Entries close May 15th. Superintendent E. H. Benjamin is in charge, and says that all holes drilled in this contest are to be "down holes" in hard Rocklin granite. Single-hand drillers will use five-eighths steel and four-pound hammers. Double teams and teams of three will use seven-eighths steel and eight-pound hammers. The time of drilling will be 15 minutes, each man to furnish and sharpen his own tools, forges and anvils to be furnished for this purpose by the mining committee.

For single-hand drilling the first prize will be \$200 and the second \$50. For double-team drilling the first prize will be \$200 and the second prize \$100. For drilling in teams of three the first prize will be \$300 and the second prize \$150. These prizes aggregate \$1000, and considerable interest will undoubtedly be manifested in the contests.

FROM all parts of the State comes the cry "a dry year." This, while affecting the agricultural interests of the State, does not directly injure the prospects of the mining

day; its purchasing power has increased and is increasing; the earning power of an invested dollar in real estate or business is less than at any time in the century, but a dollar will to-day buy more of anything that is for sale than it would one year, or ten years, or fifty years ago.

This naturally inures to California's present and permanent advantage, and it is a matter of congratulation to the nation that in these troublous times when the world is draining gold away from us that there are natural storehouses of the yellow metal to be unlocked. In the present crisis 'tis the country's salvation.

THE gathering of the "Industrials" at the National Capital elicits countless columns of editorial comment, including advice, prophecy and denunciation. In general there seems to be a confounding of cause and effect. All that the present movement needs to make it formidable is an efficient leader; were he to appear there would be real danger. So far there is no coherence in the plan. To attempt to make party or partisan advantage of the movement is mischievous and only augments the probability of grave trouble.

THE fact that France has a Presidential election next November excites envy in the minds of many in this country.

"MINERS' DAY," May 22d, at the Midwinter Fair will be a big day. Preparations are making to have it an occasion worthy of remembrance, and there is considerable interest in the coming event.

THE *Monthly Messenger*, published at Kansas City, comes to hand, making the editorial claim that it is "endowed with power from on high." That, if so, ought to be a pretty good "pull" for any kind of a messenger.

ELSEWHERE Mr. Almarin B. Paul discusses "California vs. Colorado Milling," with characteristic positiveness. Long observation and close observation have given him practical ideas on this subject, and in this as in kindred subjects intelligent discussion always results in progress.

IT is reported from the City of Mexico that a retaliatory measure against the United States, England and other anti-silver countries is being considered. The plan is to increase the Mexican import duties 25 per cent. A strong combination of the Mexican and Central American republics is hinted at. Mexico is not in a condition to "retaliate" on any country, nor is retaliation good business. Co-operation is better and more satisfactory in the long run, or the short run.

Needlessly Worried.

The Chicago *Tribune* has been reading its MINING AND SCIENTIFIC PRESS with more than ordinary care and is in a state of mind. The unusual activity in gold mining in this State causes the *Tribune* to think that it thinks that there is to be an overproduction of gold, and that the yellow metal is to depreciate in purchasing power. The *Tribune* has long talked of pig tin, pig iron, pig silver, and now fears it must talk of pig gold. It cites the gold output of the State in an argument that there is now less use than ever for silver. The *Tribune* seems as little acquainted with the law of supply and demand as the Arabs at the sack of Samarcand, when, after looting the treasure house, they went around crying, "I will give a great deal of this yellow metal for a little that is white." The *Tribune's* worry about gold is as far from the facts as its frantic sophistries regarding silver. The next thing it will discover will be probably a plethora of diamonds, depreciating the market.

The output of gold will not *per se* decrease the demand for silver; the world grows as well as moves, and our Chicago contemporary should adjust its views in consonance with the wide limits of the subject.

Times Out of Joint.

Men are marching in an aimless way toward the National Capital with a vague idea that "the Government" must do something for them, in ignorance or forgetfulness of the fact that "the Government" is not an institution apart, but is the will of the people, their will, and the will of the rest of us. Their idleness is partly their own fault, partly their own misfortune; they have rights and wrongs; some of them beat their way out here and are now returning.

Meanwhile the banks of this city and all over the country have more idle money than they know what to do with; the same as there are more idle men than the country knows what to do with. Money cannot be loaned at six per cent; idle money goes begging for investment, while idle men go begging for work—men and money alike seeking employment.

The cause of all this is lack of confidence. Confidence is a plant of slow growth and is quickly stunted. The present paralysis is occasioned by a general fear, a widespread distrust, a universal intention to do nothing, risk nothing till the future develops.

In the minds of millions is a vague, shadowy notion that has never assumed the dignity of a thought, that nothing is now safe but ready money; nothing sure but actual coin, and that in shape to be held and handled; hence securities are valueless, real estate depreciated, enterprise languishing and business stagnant. Every one is striving to correctly predicate the future and all are seized with the idea that some change is impending whereby they can profit if they only have the ready cash to utilize when the change is manifest.

This would appear to be the reason for the present abnormal state of things—men and money both out of work—each needing the other, yet repellent instead of mutually beneficial.

The great, general, constant law of supply and demand seems suspended, and in this lies the abnormal element of the situation. The law of supply and demand is the general fundamental law underlying all else; it is the mainspring of all business; it is a measureless force; a constant impulse. Demand was created for supply and supply was created for demand, and they have the same affinity for each other that oxygen has for fire. What injures the one, injures the other.

Natural law governs all things mundane, including supply and demand; and, though the times are out of joint and there is a dreadful disquietude and unrest, yet there can be at the worst only a temporary suspension of this natural law—a constant force of nature that can no more be suspended or repealed than can the law of gravitation. It is claimed that three things must first be settled—the tariff must be assured, there must be restriction of immigration, and an increase in the volume of the currency; but beyond and above all these is the need of confidence and the resumption of the interchange of the law of supply and demand. All else is a makeshift, and the business world will not revolve as usual on its axis till there is an equilibrium. Natural law is the rule of the universe, and is the only foundation upon which man can build.

The Latest Silver Proposition.

The fact that nothing is ever settled until it is settled right is exemplified by the universal interest manifested by Europe in the silver question. Bimetallism is as much the leading topic in the old world as the tariff or the march of the industrialists in the new. The leaders of finance in France, Germany and England are giving their best attention to the present problem.

Next Wednesday an international bimetallic conference will be held in London. It will be a practical effort to settle upon a definite line of action. Just at present the proposition of Dr. Arendt appears to meet with the most approval. It is this: That the United States, England, Germany and France shall agree to receive and keep, free of charge, silver bars weighing five kilogrammes each, and shall issue gratuitously certificates against the same, these certificates to be exchangeable for the bars. The price of the bars would be fixed annually by a majority of the States concerned, whose representatives would meet every October. He proposes that at that annual conference each country named shall have one delegate for every million of its population; that is, the United States to have seventy delegates; England, thirty-nine; Germany, forty; France, fifty.

The objections to this scheme are too manifest to need recital. It is not likely that the idea will be given more than quasi endorsement. But it is something to see that our European brethren are doing some walking themselves. This country is not the only one deeply concerned in the correct solution of the silver problem.

There is considerable inequality in the per capita circ-

lation of currency in the four nations referred to, as the following table shows:

	PER CAPITA CIRCULATION.			
	Gold.	Silver.	P. per.	Total.
United States.....	\$9 01	\$9 18	\$6 15	\$24 34
England.....	14 47	2 63	1 32	18 42
Germany.....	12 12	4 26	2 16	18 54
France.....	20 52	17 95	2 09	40 56

The amount of gold and silver produced by each country must also enter into the equation.

However, the result of next Wednesday's conference, which is at once a political and financial gathering, will be awaited with considerable interest. It is as important to Europe as it is to America.

Assaying Concentrated Sulphurets.

TO THE EDITOR:—In response to some inquiries of professional assayers as to the method followed by the writer in assaying concentrated sulphurets for gold and silver, the following remarks are self-explanatory: (291½ grains of ore constitute an assay unit; every assay prill of 1-100 grain represents one ounce of metal.)

The sample is not roasted, but an alkaline sulphureted slag is avoided in smelting, by oxidizing nearly all, but not the whole of the sulphur by nitre, depending upon the complete conversion of the galena to metallic lead by means of iron. Sufficient silica is also added to decompose the sulphate and arsenate alkaline formed on deflagration and convert it into a sin gulo silicate. A very basic iron slag is avoided on account of its high specific gravity.

The assay mixture used and kept on hand, which is also used, but in increased proportion, for quartz and earthy gold and silver ores, has the following composition: One part litharge, one part bicarbonate of soda, one-tenth part flour. It needs sieving through a wire sieve.

The concentrated sulphurets are dressed for assay as follows:

I. Pure pyrites.

1 part (291½ grains) sulphurets.

1 part quartz sands.

3 parts assay mixture—900 grains, which can be measured off with sufficient accuracy in a glass of correct size.

1½ parts pulv. nitre.

Add one or two heavy nails and give a liberal borax cover.

II. Concentrates carrying 50% of pyrites—Iron.

1 part of ore.

½ part of quartz sands.

3 parts assay mixture.

¾ parts pulv. nitre.

2 heavy nails with liberal borax cover.

Melt for 30 minutes in a hydro-carbon furnace with strong final heat. The soft lead button should weigh about 375 grains. Special attention is called to the importance of not adding too much silver to the assay prill for parting, on account of loss of gold by too fine a subdivision—three parts of silver to one of gold as near as possible.

Auburn, April 26, 1894. G. F. DEETKEN, M. E.

Personals.

SUPT. GORHAM of the Potosi, Chollar and Bnllion is again on the Comstock.

JAMES E. MILLS, a mineralogist in the employ of the F. L. Ames estate and a Boston syndicate, is in the city. He has for some months been examining the gold resources of Plumas county.

W. F. HILLYER of Leavenworth, Wash., reports good gold-producing mines in his section. Several claims are in process of development; and when six months ago there was but one house, there are now 700 people.

SECY A. W. HAVENS of the Con. Cal. & Va. Co. has just celebrated the twentieth anniversary of his incumbency of the secretaryship. This enormous sum of \$54,000,000 has been paid to stockholders in dividends by Mr. Havens.

JUDOR WALSH was buried last Saturday. He was a pioneer, and 43 years ago was manager of the Gold Hill quartz mine at Grass Valley. He was prominent in the early years of the Comstock excitement. The Judge was over 80 years old at the time of his death.

REV. MR. NICHOLAS of Sonora is said to have the only chnroh in California that has a gold mine under it. At the Episcopal convention in this city last Wednesday his bishop said: "The principal thoroughfare of Sonora is the richest street in California. There is so much gold under the main street that men have offered to construct a complete sawyer etym in the town simply to get the quartz which may be dug up. The poorest people there walk over millions of dollars' worth of gold daily."

WASHINGTON officials view with disquietude the approach of the "Industrialists." The marshal of the district has issued a proclamation warning them to keep the peace; two resolutions have been introduced in the House—one providing for the maintenance of the Industrialists in Washington; another making the members of the Industrial Army soldiers of the regular army for one year, and employing them on public works. Ridiculous legislation seems to have reached its limit.

General Mining Notes.

THE McQuay claim at Elk Creek, Colo., is reported to be shipping ore which gives returns of \$150 in gold to the ton.

THE time for performing assessment work on British Columbia mineral claims during the current year has practically been extended to July 31, 1895.

LEADVILLE, COLO., is producing from its gold belt 500 ounces of gold daily. This product is derived almost entirely from four mines, three of which have been opened within the last six months.

THE *Mountain Echo* says the rumor that has gone abroad to the effect that the Utica Mining Company of Angels has sold its interests in Angeles to an English syndicate is wholly without foundation.

THE Baltimore Mining and Milling Co. has been incorporated by W. H. Coburn, S. A. Riley, H. H. Jones, E. J. Edwards and E. K. Gny, to operate in El Paso county, Col., with \$1,000,000 capital stock.

PHENOMENALLY rich gold discoveries are reported in Dixie district, near Boise, Idaho. Rook is said to have been found that runs thousands of dollars to the ton. Very rich placer ground has also been found.

THE Nevada City *Herald* is informed that a party of about 50 mining men, all capitalists, are coming from Utah to be at the Midwinter Fair on Miners' Day, and that a dozen or more of them are going to Nevada county afterward with a view to making investments.

THE Seminole Gold Mining and Milling Company of Summerville, Tuolumne county, has incorporated. The capital stock is \$300,000. The directors are Emory J. Landers, J. T. Rooney and T. W. Wells, of Sonora, W. B. Moore of Alameda, and Ransom W. Rockwell of Seattle, Wash.

THE Ross Hill Gold Mining Company has been organized by James M. Wishart, E. H. Wishart, Noah A. Walker and J. M. Davis of Oakland, and H. M. Shaw of San Francisco, with a capital stock of \$100,000, of which \$60,000 has been subscribed. The principal office of the company is in Oakland.

THE Americans Gold Mining and Milling Company was lately incorporated in Gilpin county, Colorado, with a capital stock of \$700,000. The Americans group of mines includes the Fisk, Blythe, Grond Hog and Columbus veins. It is the purpose of the company to build and equip a stamp mill to reduce the ores from those mines.

THE *Tidings* hears that a company is to be formed in Grass Valley for the purpose of purchasing a complete diamond drilling outfit, to prospect the ledges in this vicinity. No doubt such a company would find plenty of work, and as these drills have been successfully used in other places, we see no reason why they would not pay here.

SUPERINTENDENT AEAIR informs a *Transcript* reporter that pipes are being laid and that the waste water of the North Star mine will soon be utilized for generating electricity to light all the mine buildings. Electricity will be especially valuable in lighting the mill and will be a convenience in the hoisting works, dry house, office and other buildings.

CRIPPLE CREEK (COLO.) MINES, comprising the Queen of the Hills, Vanadium, Hidden Treasure and Baby Ruth, located on Battle Mountain adjoining the Anna Lee and Portland, have been sold for \$100,000, to W. S. Stratton, James Burns, James Doyle and John Harnan, owners of the Portland, Bohail and Scranton. The new property will belong to the Portland company.

COCHITI is the location of the latest ore find in New Mexico. It is about 40 miles southwest of Santa Fe, on the west side of the Rio Grande river. The ore is quartz, some of it being mixed with iron and copper pyrites. It is high grade and carries about equal values in both gold and silver. The veins are large, and in granite, or in contact between granite and porphyry. Several hundred prospectors are there now, the most of them coming from Colorado.

AN eight-inch pump is being put in at the Nevada City mine and will be used later on to pump water up to the drain tunnel. It is the intention of Superintendent Shoecraft to sink the shaft another hundred feet, and a station is now being made at the 500 level. The work of sinking will commence shortly. The mine is looking fine and very rich rock is being taken out, some of it being so rich that it is not milled, but is sent to the Selby smelting works to be reduced.

A FORMER Nevada writes to the *Reno Gazette* as follows, of the Broken Hill mines in New South Wales: "We have, without doubt, the greatest silver-lead mine in the world, and notwithstanding the very low price in silver and lead, we continue to pay \$240,000 per month in dividends. Our operations, however, are on a very large scale and we are treating about 10,000 tons of ore per week. Our output of silver is on an average a little over 250,000 ounces per week, and our output of lead about 900 tons per week."

THE National Bank of Savannah recently forwarded a silver dollar which had been defaced in a fire, but was of full weight, to the redemption agent at Washington. This agent sent it to the Philadelphia Mint as undercurrent coin. Superintendent Townsend at Philadelphia remitted 43 cents as its bullion value. The bank official wrote to him, pointing out that the silver dollar was of full weight and only slightly defaced. He failed to see why he should receive only 43 cents for it. The reply came that defaced coins were redeemable at only their bullion value.

ACTIVE OPERATIONS are soon to be commenced on the ochre mine, says the *Calaveras Chronicle*, about two miles from Valley Spring. A combine has been made of all the leading dealers in paints in San Francisco. Machinery will be put in place to grind the ochre and it will be shipped in barrels to San Francisco, where it will be mixed and made ready for use. The ochre obtained is said to be of an extremely fine quality and deeply colored, yellow predominating, although red, green, blue and black have been found. When once in operation the "paint" mine will give employment to quite a number of men and its owners will be well paid.

THE San Juan placers in southeastern Utah have been abandoned. Machinery was put in at a considerable expense,

but failed to extract the gold. There is gold in paying quantities in the placers, but it is almost as fine as flour and will have to be put through a process of amalgamation before it can be saved. The gold, unlike most placers, is in a cement formation that is almost impervious to water, and the methods of washing and sluicing will not dissolve the cement. These placers will have to be worked in a similar manner to gold-bearing rock, by the usual milling process, before the fine gold can be successfully extracted from the cement.

SAMUEL A. ALLERTON has instituted proceedings in the United States District Court at Sioux Falls, S. D., for the recovery of \$3,342,270 from the Homestake No. 2 Mining Company. The claim which the complainant puts forward was assigned to him by James J. Sullivan of Chicago, who purchased the mine in 1878, paying \$10,000 down and promising \$30,000 more. The mine proved of more value than was hoped for by the prospectors and Mr. Sullivan's purchase was repudiated and he assigned the claim to Allerton. An accounting of the profits that have accrued from a 52 interest since 1878 is demanded. Offers of settlement have been made by the company, which range from \$2,000,000 to \$3,000,000.

SAYS the Virginia *Enterprise*: Colonel Curtis looks upon the extension of the Central tunnel westward in Ophir ground as one of the most important movements made in the history of the Comstock lode, as it will explore a region the surface workings of which proved prolific in gold-bearing quartz. The tunnel will penetrate the ground formerly known as the Burning Moscow below the old levels, with a highly favorable prospect that an important ore discovery may result. A development in that direction would be followed by the immediate extension of the Sntro tunnel under Mount Davidson and all of the principal companies on the lode would extend explorations westward in entirely new ground.

THE mail route between Trinity Center and old Cecilville, over Salmon mountains, has been let to a party in San Francisco. A Trinity Center correspondent of the *Weaverville Journal* says: We understand that the rate is less than \$1500 per annum for bi-weekly service of 45 miles each way. This is a snowshoe route, and will require two men for two months on snowshoes, at \$75 per month each, and if the San Francisco party is one of the men, he will think that carrying the mail on snowshoes over mountain trails is not a very enjoyable pastime. A little practical experience in carrying the mails over our mountain routes is about the only remedy that will serve to check outsiders from putting in bids for mail contracts at starvation rates.

AN Olympia, Wash., dispatch announces that Don Carlos Bnell is going to Westport, where he is erecting a plant to recover gold from the black sand along the coast of Oregon and Washington. The plant is located at Westport and consists of a number of tanks and a powerful electric battery. The gold is dissolved from the sand by a solution discovered by Bnell, drawn from the tanks, and by the application of electricity the gold is separated. He says the sand will yield \$10 of flour gold to the ton of sand, and that enough exists on the Oregon and Washington beach to pay the national debt. He also has tests of platinum which he claims yields even better than gold. If Don Carlos has a successful method of extracting the gold from the black sand, Rothschild will be a pauper alongside of him. The gold is there all right enough, but of the thousands who have tried, no one has succeeded in getting the gold in one heap and the sand in another.

SO FAR, the California Debris Commission has issued permits under the Caminetti act to thirty-four mines. A regular report of the amount of work done is required from the manager of each mine. The one showing the largest amount of work is the Blue Gravel, at Smartsville, Yuba county, operated by the Excelsior Water and Mining Co. The monthly washings of this mine amount to over 60,000 cubic yards. The smallest is the Tanner Ravine mine, near Brownsville, in the same county. During the first month's operations after resumption of work the washings aggregated two cubic yards, and during the second month, two and a half. Two men and a boy are the working force there. So far, fifty-four applications have been made. The number is lessening, and it is thought there will not be many more this season. During the week a permit was issued to the Green Meadow mine, near Glencoe. Estimate is made that the hydraulic work now in operation under official permits is about ten per cent of the amount of that kind of mining in operation in this State before the anti-debris agitation.

General News Notes.

TO BOKEN there have been over 1,200,000 admissions to the Midwinter Fair.

FOUR THOUSAND Chinamen have registered in Boston under the Geary act.

GOLD to the amount of \$7,000,000 went to Europe from New York during the week.

COLONEL BAAOKINAINGA says he is a pauper and can't pay the \$15,000 damages awarded to Miss Pollard.

NEARLY 100,000,000 bushels of available wheat in the United States and Canada is reported by Bradstreets.

THE San Francisco Democracy have denounced Hill and Geary and have endorsed the Wilson tariff bill.

WHAAT has touched the lowest point on record at Chicago—57½ cents. The bears predict it will go to 50 cents.

DRAINING the week over 100,000 coal miners struck in Ohio and Pennsylvania. So far both sides are unyielding.

TRAINS on the Fort Wayne road now make the distance between New York and Chicago in eighteen hours.

THE largest gold coin in circulation is the "loaf" of Anam, which weighs as much as 325 United States dollars.

THE Great Northern railway strike is over. Concessions were made by both sides, and trains are running as usual.

CLAUDIA HERBASA, aged 120 years, died on Telegraph Hill in this city last Saturday. Her age was well authenticated.

THE property of the Nicaraguan Canal Company at Greytown has been seized by the Nicaraguan Government and sold for \$75,000.

THE passenger steamer Los Angeles was wrecked at Point Sur, on the Monterey coast, last Sunday morning. Eight lives were lost.

A new aluminous phosphates mineral, having some of the qualities of turquoise, has been discovered in the Camp Floyd district, Utah.

DRAINING the recent fiesta at San Diego joy was unrestrained, cowboys riding into saloons and assuaging great thirst without dismounting.

THE Board of Prison Directors have authorized Warden Hale of San Quentin to sell 3,000,000 jute hags, which he has on hand, for 5½ cents each.

MAJORA RATHBONE, of this city, last Saturday received a check for \$100,000 from M. Goguenheim & Sons, for his share in the Tepalaz, Mexico, copper mine.

IT is estimated that the new tariff bill will reduce revenues on wool and metal manufactures about \$36,000,000. The 1893 revenues were about \$58,000,000.

A MAXIMUM speed indicator for electric railways has been invented. An alarm bell in this device rings whenever the velocity for which it is set is attained.

AN execution for murder and the conviction of an assassin for murder in the first degree convinced San Franciscans on the 20th that hanging isn't "played out."

HOGAN's branch of the "Industrial Army" stole a Northern Pacific railway train at Butte, Montana, and went flying along to St. Paul at the rate of forty miles an hour.

THE Fleming-Ayere shingle mill, near Seattle, Wash., the largest concern of the kind in the Northwest, was totally destroyed by fire last Sunday night; loss, \$50,000.

"BILLY" MCGAHERAN, famous all over the United States by reason of his claim to the New Idria quicksilver mine, died in the hospital at Washington, D. C., last Tuesday.

AT Yaquina Bay, Oregon, collection district, last year, it cost at the rate of \$4240 to collect \$1.00. During the year 25 cents was collected at a cost to the Government of \$1060.

GEN. WEAVER, of Iowa, has been nominated for Congress by the Kansas Populists, but the inducements are not sufficient, and the General refuses to move to the Sunflower State.

IT is calculated that the stoppage of silver mining reduced this country's annual supply of gold by one-third, as about 33 per cent of the yearly yield of gold is taken out of silver mines.

THE Industrial Army still goes marching on. A new delegation has started from Boston. The Coxey men have arrived at Washington and will camp at the foot of the Washington monument.

THE House Committee on Coinage, Weights and Measures has side-tracked the Meyers' compromise silver bill and decided to report favorably Bland's bill for the free coinage of silver.

THE United States Supreme Court has decided that lager beer is not a "spirituous liquor" within the meaning of the statute prohibiting the introduction of spirituous liquor or wine into the Indian Territory.

THE Northern Pacific and the Union Pacific roads have pooled on the freights from the Cœur d'Alene lead-silver mines. The ore or concentrates are sent either to Denver or Pueblo, and the freight tariff is almost prohibitory.

IN the contest for the county cup for the best mineral exhibit at the Midwinter Fair, Nevada county has passed the 225,000th vote; El Dorado county is second on the list, with Placer, Amador and Tuolumne in the order mentioned.

THE *Western Democrat* of Missoula says that it has it on pretty reliable authority that Marcus Daly has floated \$5,000,000 in bonds of the Butte, Anaconda and Pacific railroad and that the money is now on the road from New York.

"THAT there are no present indications of any attempt to foreclose the Government's mortgage on the Pacific railroads," says Senator Brice, "but much depends upon what the security-holders behind the Government agree to do."

THE Southern Pacific Company operates a total of 7867.14 miles, of which 4470 are proprietary lines, 2128 leased lines and the balance affiliated lines. The gross transportation earnings for 1893 were \$53,946,667, and the operating expenses \$34,692,402.

JAMES SALOMAN, the celebrated banker, died at Coronado last Monday. He was a California pioneer and owned largely in the Anglo-American bank. He left a fortune estimated at \$12,000,000. His firm placed the first United States bond issue in Europe.

FROM South Africa comes the report that John Hays Hammond, who left here last summer to take charge as consulting engineer of the Rhodes-Barnato Syndicate gold mines, is leading an exploring party on a 1600-mile trip through the wilds of Matabeleland.

COMPARING British production with the output in the United States, the American output of pig iron in 1892 was 2,540,110 tons greater than that of Great Britain; during 1893 it was but 294,661 tons more. This decrease was almost entirely in the last half of the year.

THE new placer fields of New Mexico are located at the confluence of the Rio Hondo with the Rio Grande and extend north to a point near the Colorado line. According to reports results are astonishing, but it is said that the average run of dirt is about \$2 per yard as it comes.

J. A. LIONTHALL JR. has made an offer to the San Francisco supervisors to dispose of the garbage for San Francisco at a cost of \$125,000. He thinks that the plant would be almost self-supporting, as the grease, which is extracted by the naphtha process, has a value of 3½ cents a pound, and the dry garbage after it is deodorized and disinfected, brings from \$12 to \$1 a ton.

THE reported discovery of a wonderful deserted city in a remote section of the Sierra Madre mountains, in Durango, has been verified by Maurice Lentow and a party of explorers. They found a secret entrance to the city and made an exhaustive exploration. They returned laden with curiosities from the abandoned residences and temples. The population of the city could not have been less than 25,000.

A DOUBLE MURDER is reported from the Dos Cabezas mining camp in Mexico. Jack Redding and David Harper, wealthy

and prominent mining men, met and quarreled over a business which they agreed to settle with their revolvers. Both men fired at the same instant and both were shot dead in their tracks. They had been partners for a number of years, and until their fatal quarrel had always been fast friends.

THE Indiana Republican State Convention last Wednesday adopted the following in its platform: "We believe in a currency composed of gold, silver and paper, readily convertible at a fixed standard of value, and entirely under the national control, and we favor the imposition of increased tariff duties upon imports from all countries which oppose the coinage of silver upon a basis to be determined by an international congress for such a purpose."

THE Postoffice Department announces that no more dropping of letters into the mail cars will be allowed. Hereafter mail will not be taken on the railroad mail cars unless it first passes through the postoffice. The order was made because so many business men near railway stations mailed their letters on the train and it made a large amount of extra work for the mail clerks, time being used in stamping letters that was needed in sorting out mail between stations.

In an article on prospective railway building the *Railway Age* states that within the last 20 years over 107,500 miles have been added to the railway system of the United States, giving an average of 5379 miles a year. Within 30 years the railway system of this country has grown from 33,000 miles to 177,850 miles, and now aggregate nearly half the total mileage of the world. A vast mileage is yet to be built, and in increase of activity in this respect is already on hand. A list of 411 lines is given, aggregating a proposed length of over 22,500 miles and representing every one of the 48 States and Territories, the speedy construction of which appears to be demanded.

California vs. Colorado Milling.

TO THE EDITOR:—Having read with more or less interest the observations as respect the two styles of mills, or, more properly speaking, the drop and speed, I feel a little like putting in a few words, although I had about made up my mind to keep out of print, for the simple reason that it has never benefited me, and I don't know as it has others.

Forty-three years ago I made my first move in California in the milling of gold ores with the crude machinery of those early days, which it is not pertinent to the question at issue explain. From my beginning to the present time I have watched and studied closely the advance in mechanical construction of mills and all the multitude of plans for saving the precious metals, and while I say to all, carry out the ideas which give the greatest pleasure, independent of others, I nevertheless will give some views which are antagonistic to the Colorado idea of milling with a slow motion and high drop.

To begin with amalgamating in the battery, with all the fine devices now to be had for saving the precious metals; outside of it, it is not so essential a matter that one should entail an extra expense by way of lessened capacity of your battery in consequence of this slow motion. The grand point to accomplish with the battery is reducing the largest quantity of ore at the least expense. Amalgamate, if desired, to the highest per cent possible, but use the battery clearly for what it is made—to crush rock. When it comes to the weight of stamps, the Colorado idea (650 pounds) I consider nearer correct, though 700 to 750 pounds is not objectionable. In 1851, in Grass Valley, Nevada county, this question was carefully canvassed by testing the work of all weights from 500 to 1400 pounds on average ore, by a number of quartz miners, of whom I was one, and after full consideration of weight, speed, drop and execution (notwithstanding our stamps were crude the weight was the same), it was decided that 650 pounds gave the best figuring, and for at least 10 years I don't know of heavier being used. From that day to the present I have not varied from this weight, though I have advanced in speed.

With all the improved rock-breakers which can reduce to, say, even a five-eighths opening cheaper than stamps, there is no necessity for such weighty stamps as 800 to 1000 pounds each. It is a waste of money in power to lift, without a compensating amount of work.

I note further in your article you state that the California mill saves 94 per cent with concentrators and the Colorado mill 89 per cent without and with concentrators it will save 95 per cent. Well, I suppose I will be bringing condemnation on my head if I say I give no credit to any such results. Independence of thought has been my failing and enemy. I will say further that there is not a mill working gold ores with simply stamps, silver plates and concentrators that does not run away in its slimes and tails at least 20 per cent of the value, and the majority of them 35 per cent, unless in exceptional cases of working specimen rock. I have made too many tests on this point to accept any such data. I do not doubt that with some tests of tails, minus the run-off slimes, assays may be had which will show a less percentage of loss; but take a 10x10 tank, full of tails, with all the muddy water and let it fairly settle, then dry, sample and assay, and see how your 95 per cent agrees.

In South Africa (Jobannesburg) they have as fine mills, with all appliances, as in California, with skilled California mill men to operate them and, as a general thing, easier

ore to work, and see what they are doing with their tailings alone.

By way of information to many, I will give the figures. For a long time they were satisfied with results, yet condition of the ground compelled the saving of their tails. They in time investigated, and found a value in them, and by degrees the mills took up the working of them, and the following is the yield of same for the respective months of 1893-94:

	Ounces.
April, 1893, the yield from tails was in gold.....	18.577
May.....	21.278
June.....	24.564
July.....	24.616
August.....	30.403
September.....	31.354
October.....	33.587
November.....	36.546
December.....	38.825
January, 1894.....	41.204

I do not, however, take South Africa milling for my knowledge or experience, as I learned the lesson long before a mill was built in the Transvaal. It is a well-known fact among old quartz men that I have harped on this loss of gold for fully 35 years—have written volumes on it—and I have observed, too, that year by year there has been an advance in the percentage saved by improved appliances. Concentrators have been a great step forward—in fact, are indispensable for the majority of ores. New processes have also assisted, and none is more in the right direction, generally speaking, than the cyanide.

California has not yet reached her ultimatum of per cent of extraction, but she is yearly advancing, and in a few years more will be in the line of perfect milling. Thorough investigation by competent men will give many profitable surprises as to what gold you don't get. We pay too much attention to crushing rock and too little to securing the value of it. I give these ideas for the consideration of mining men. I know they will give a return of criticism for me. All such declarations, however, inspire investigation, and investigation will give improved results. Yours,

ALMARIN B. PAUL.

Room 4, Crocker Building, S. F., April 26, 1894.

Mexican Methods of Mining.

J. Howard Palmer, B. A., in London *Mining Journal*.

In a preceding article some mention was made of the frequent use of long adits in the mines, and of the steadiness and perseverance with which the Mexicans prove their lodes by this method. They have, however, still a good deal to learn in adit driving; the rise of the tunnel necessary to give proper drainage is generally a matter of guess work, and it never seems to enter their heads that it is more economical to drive straight ahead than to go winding about; the adits are apt to resemble a series of elongated S's, and their height and width are by no means fixed quantities. After all, these are not very grave faults, for if the vein shows favorably in the roof, or to the right or left, it is surely wiser to spoil the appearance of the work, rather than miss payable ore or lose the vein.

Rock drills and air compressors are beginning to come into use in Mexico, but the advantage of using them is somewhat doubtful, unless there is great urgency for the completion of the work in hand. Fuel is generally so dear, and not likely to become cheaper, that the comparative costs of machine drills and hand labor work out in favor of the latter for ordinary work. In fairly hard ground a gang of Mexicans will drive from three to four meters a week, at an inclusive cost varying between \$30 and \$40 per meter. Two air drills will, perhaps, accomplish ten meters per week, but each meter will cost from \$80 to \$100. Half of the expense of driving by machines will be incurred for fuel, upkeep of machinery, and the whole question of hand vs. machines resolves itself into one of the price of combustibles. When it is necessary to speedily unwater a mine by an adit, or to reach an already proved deposit in order to put a concern on a paying basis within a certain time, in such a case, of course, the advantages of using rock drills are incalculable; but under ordinary circumstances they are rather luxurious than otherwise. A further difficulty in the use of machine drills lies in the inability of the native miners to work them. Skilled drillmen have to be imported from England or the States, and if they fall ill or fail to agree with the Mexicans, the work must suffer until fresh men can be procured. Big mines, however, in which development work has to be well ahead of the stopes, can easily afford an installation of air-compressing machinery and drills, and the gain in time and efficiency will amply compensate for the increased expense of working.

The Mexicans are not very good timbermen, and the reason is that they do not have the necessary experience; timbering is not often required in the deep silver mines. In working the dry sulphide ores, at any rate, the veins are very compact, and the country rock being of primary for-

mation very seldom requires support. When there is any danger of a run the Mexicans prefer to build walls or arches of strong masonry, and in this method of securing the workings they are very clever indeed. In many districts timber large enough for mining purposes is simply not to be obtained except at prohibitive prices, and masonry is much cheaper and lasts forever. Still, timbers are often used in patches of wet and disintegrated ground, the spaces between them being filled in with poles two or three inches in diameter, placed closely together and supported by the large sets.

Stoping in Mexico is often carried on very carelessly, and without much regard for safety; in the eagerness to get out every available scrap of ore, pillars are taken down which should never have been meddled with, and a mine thus becomes dangerous to work in long before it is exhausted, and future development means much avoidable expense and trouble. The native mining is at its worst when the ore is found in rich stringers, between one and two feet wide. When this is the case, mining is apt to degenerate into "burrowing," without plan or system, and one finds drifts and winzes, through which it is scarcely possible to crawl, running in all possible directions. If an English company takes over a mine like this, perhaps the best way is to disregard the old workings altogether and start afresh well below them. It is no use looking for ore where Mexican miners have been before, for they scrape a vein as clean as dogs picking a bone, and only give up because water beats them.

Vertical shafts are not very common in Mexico, and a descent of one is not a particularly pleasant experience. Cages are rare and man engines are unknown, so the usual way of going down is to be tied to the cable. The means of support is a piece of strong webbing, broad in the middle and gradually diminishing to the thickness of a rope at each end, and called a *caballo*. The broad parts go around the person, and the ends are secured to the cable by a dove hitch or similar knot. One is tied up at the top and swung out over the mouth of the shaft, with a sensation, at first, of being "turned off" by Jack Ketch. Going down, it requires some practice to keep clear of the sides, which are not so squared off as they might be, and the trip probably ends with being soured in the dirty water of the sump below. The ordinary miners are not allowed to use the shaft, but have to go up and down by the ladder-way, which winds, more or less, spirally around the shaft and entirely distinct from it. By law every mine has to be provided with two outlets, and as fast as a shaft is sunk a ladder-way is made as well. It is not surprising that the Mexicans prefer to make use of shafts as little as possible so long as the means of hoisting men and material are so primitive. There are, however, some splendid shafts of entirely native construction. The shaft, for example, of the famous Valenciana mine at Guanajuato is 400 meters deep and 8 meters by 12 throughout, and employs six different hoisting engines, with cages and tonneles. Valenciana, however, is perhaps the largest and oldest mine in Mexico.

The Royal Gold Mine.

The greatest gold mine in Montana is now the lately developed Royal, at the head of Boulder creek, a small stream that puts into Flint creek, not far from the town of Drummond. This mine is now yielding a net profit of \$17,000 per month. The owners have spent \$70,000 in its development and in the erection of a ten-stamp mill, and a million dollars in cash would not buy it to-day. In fact it is paying one per cent a month on \$1,700,000, and it has ore enough in sight to last five years. There are probably dozens of almost equally valuable gold leads in Montana, hidden in the mountains. To develop a prospect into a mine takes a good deal of money and a good deal of courage. The men who discover the prospects have nerve enough but they rarely have any money. In many cases half a lifetime is spent by the owner of a good prospect trying to persuade capitalists to put money into the work of opening it up and demonstrating whether it is worth anything or not. The chief owner in the Royal is Nelson Bennett, of Tacoma, Washington. He made a fortune boring the long tunnel through the Cascade mountains for the Northern Pacific, and he increased his wealth by a lucky deal in Fairhaven, from which he got out in time to avoid the collapse which nearly ruined that town. Then he bought a big hotel and a morning newspaper in Tacoma, and just before the financial panic last summer he purchased a controlling interest in a bank. The bank went to pieces; the hotel did not pay and the newspaper sunk money, as most of the dailies in the West have done during the past year. Just in time to help Bennett out of an uncomfortably tight place came the rich strike in his mine. The Royal is now well developed by two tunnels and a shaft, and it shows the most remarkable body of rich gold ore known to exist anywhere in the United States.—North-west Magazine.

Mines and Mining in Grass Valley.

Written for the MINING AND SCIENTIFIC PRESS by Samuel Butler.

On several previous occasions attention has been directed to the fact that Grass Valley offers the best inducements for judicious investments of any mining district in California. We do not make this assertion with any degree of braggadocio, or for the purpose of misleading the unwary speculator. A close study of the history of the city and the geological formation of its mineral deposits must forcibly convince the intending investor of the truth of the above assertion. From its inception to the present time this district has enjoyed a steady and continuous growth. To-day it far excels in prosperity and population any previous era in its history. Our quartz veins are so great in extent and wealth that we regard our mines as being permanent and not subject to the fluctuations experienced in other and less favored mining districts.

In proof of these assertions I would like to reproduce an interesting interview which I recently had with a prominent capitalist, who has invested several hundred thousand dollars in this county. This gentleman, for reasons not necessary to divulge, requested that his name be withheld from publication. The substance of the interview is as follows: "Grass Valley is an ideal city. In my mind it is first and foremost in every respect of any mining town on the Pacific coast. No other mining district offers the same inducements and advantages west of the Rocky mountains. The railroad facilities are perfect. Where on the Pacific coast can you find a mining town so highly favored with railroad transportation? Consider the great saving effected by these advantages every year—something unknown to mining districts in more remote parts of the State. But this is only a small portion of the inducements held out by this district. However much we may desire cheap transportation in the development of our mines, the overwhelming attraction to capitalists is rich and productive ledges. Transportation is a secondary consideration to this. Without such prizes to offer it would be impossible to secure capital; but Grass Valley possesses this inducement in a degree not elsewhere found on the coast. Where can you find mines that have been so productive, considering the depth attained? Where is there a similar area in the State that has produced a like amount—\$120,000,000? There may be a few single exceptions, such as the Utica mine of Calaveras county—probably the only solitary exception at this time—but taken altogether there is no district that approaches in wealth of production the quartz-crowned empress of the Sierras. Here is deposited a network of veins unequalled in extent and wealth by any other locality in the State. In some cases the surface has only been scratched, while in others development work has not been conducted to any great degree. When these ledges are properly developed, who shall estimate the prosperity of Grass Valley? With cheaper motor power the future of this district is assured. What most surprises me is the fact that Grass Valley has not experienced a boom long ago. Had the district been located anywhere else, a great boom would have been precipitated years ago. But the policy of silurianism followed by the majority of your citizens has had a tendency to keep the merits of your mines in seclusion. It has also prevented capital from entering the district and developing the mines now idle. The abandonment of these old 'forty-nine' ways and the adoption of a more enterprising and progressive policy is greatly needed and would be highly beneficial to the best interests of the city. Capital is beginning to turn its attention to Grass Valley, and it rests with your citizens as to the kind of treatment it shall receive. In conclusion, I may say that I have visited nearly every mining city on this coast and I have invested in almost every State and Territory, but nowhere have I been so favorably impressed as with the great natural and artificial advantages offered by Grass Valley."

This is only one of the many eloquent tributes paid to this district because of its wealth and worth.

A short time ago, in company with A. W. Stoddart, superintendent of the Centennial mine, who is regarded as one of our foremost mining and mechanical engineers, I made a tour of the Osborne Hill mines. Osborne Hill is so well known to a large number of the readers of the PRESS that I deem a description of its topography and geological formation entirely unnecessary. In the very early history of Grass Valley this hill was one of its most noted and prosperous environments. It became a beehive of industry. Everywhere the hill was dotted with prospect holes, and miners were seen busily engaged extracting the precious metal. And then when these "holes" had reached what we consider a superficial depth, and water had been encountered, they were abandoned because of the crude methods in vogue at that time. Their intrinsic value had not diminished one iota. This was the

cause of the abandonment of a large number of promising mines in the early days. Attention is now being directed to these abandoned mines and their future development is a certainty. There are over 20 properties on this hill worthy of serious consideration at the hands of capitalists, and the successful development of the Osborne Hill, Centennial, Electric and Conlin mines cannot fail to bring this environment into prominence and be productive of good results.

The Centennial mine is situated on the summit of Osborne Hill. Although only two and a half miles from this city, it has an elevation of 3000 feet, making it 600 feet higher than Grass Valley. From the summit of the hill a splendid view of the surrounding country can be secured. Several points in Placer county are clearly observable. The Centennial is among the oldest locations in this district and has been worked at intervals since 1851. It was formerly known as the Wide Awake, and has an extent on the vein of 3000 by 600 feet. The course of the vein is north and south, having an angle of about 30° west. The average width of the vein is one foot. On the property there are two incline shafts, one having a depth of 500 and the other a depth of 650 feet. Operations are being conducted through the last-named shaft. Six levels have been opened with a maximum length from the shaft on the south of 200 feet and on the north of 600 feet. At the present time work is confined to the 650 levels north and south; and when the proper distance is reached, it is the intention of Mr. Stoddart to put an upraise and make connections with the original shaft, which is about 600 feet from the one through which developments are now being carried on. This action of the superintendent is justifiable, and will greatly facilitate the development of the mine.

It is evident that when the mine was reopened in 1876, by a company of practical miners, through the old shaft, operations were confined to the south of the shaft. In their anxiety to work some rich "stringers" encountered south of the shaft, the northern extremity of the ledge was neglected; and at the present time on the north side of the shaft there is a vein averaging a foot in thickness in purely "virgin" ground. The last crushing taken from this vein was in close proximity to the shaft and paid \$35 to the ton. From 1876 to 1882, \$500,000 was extracted by a party of miners, although the mine was worked on a very meager scale. On the property there is a commodious and substantial hoisting works fully equipped with all the modern appliances. There is ample room for a ten-stamp mill which it is the intention of the company to erect this summer. A six-inch pump relieves the mine of its water.

The superintendent informed your correspondent that when connections are made with the 650-foot level the old shaft will be repaired and a new hoisting works erected thereon. This will greatly add to the advantages now enjoyed and will be instrumental, from present indications, in developing an extensive property. The Centennial Company may be congratulated on the possession of a very promising property, and if they are "wise in their day and generation," they will spare no expense but make the development of the mine rapid and complete.

Developments are being pushed rapidly at the Osborne Hill mine, under the efficient superintendency of Mr. L. P. Goldstone. The Osborne Hill mine was located in 1850, and soon became famous as a gold producer. But, like most other mines, it has encountered difficulties. At a depth of 450 feet it yielded over \$2,000,000. The shaft is now at a depth of 700 feet, and drifting is being prosecuted north and south on the 500 level. The vein averages a foot in size and the ore is worth about \$35 a ton. About 35 men are employed at \$3 per diem. It is the intention of the Osborne Hill Company to erect a 20-stamp mill this summer. The owners of this mine are very fortunate, as the impression prevails here that it is destined to become one of the most extensive mines in the district.

The Electric mine is also situated on Osborne Hill, and, like most of the other mines in this district, has been worked at intervals. The property is regarded as being a very valuable one, and promises, when properly developed, to be very remunerative. The mine is being developed by Mr. Dan Coffin, the superintendent, and about 25 men are employed. The shaft has reached a depth of 400 feet, the ledge being of good size and fair quality. Drifting is in progress at the 300 levels, north and south, a long length of stoping ground being in readiness for the mill when it starts. A new ten-stamp mill (ten more stamps can be added at any time) has been erected, and when it is in operation it will give employment to a large number of men. The prospects of the Electric are very flattering.

The large circulation which the PRESS enjoys in every mining district throughout the coast has induced me to

utilize a little space for the purpose of warning miners not to come to this city at the present time. While it is true that Grass Valley is enjoying an era of unprecedented prosperity, and that it is to-day the most extensive mining camp in California, it is also true that the city possesses her quota of unemployed. Since the suspension of the silver mines men have been flocking here from every point and in every conceivable manner. The supply of labor has been far greater than the demand, consequently our streets are dotted with idle men. The percentage of idle men is probably greater than at any time in the history of the city, and to prevent others from still further swelling the number this note of warning is given.

Grass Valley, April 25, 1894.

SAMUEL BUTLER.

Of Practical Value.

Mr. A. S. Hallidie, president of the Mechanics' Institute of this city, recently delivered an address at the annual meeting of that body, which is replete with sound sense and practical suggestions. In the course of his remarks he touched upon the topics of local industries, manual labor, and trade schools, and spoke as follows:

The employment of men at a fair rate of wages is the solution to the hard times we have been experiencing. The Mechanics' Institute recognizes this, and emphasized it by the reception tendered to the Union Iron Works. I do not think that the importance of this fact has impressed itself on the people of San Francisco, yet for the last three months large sums of money have been raised to give work to the unemployed, and it has been seen how willing the majority of men are to earn, rather than to beg, their bread. If the lesson of the present condition of affairs can be made effective in this community, the money spent in thus enabling so many men to earn their bread will be well invested. Sufficient encouragement has not been extended to the local industries, and many have been driven from this city through the indifference of the people, who have failed to recognize the fact that, by giving preference to goods manufactured and produced by local industries, they keep the men and women of the city remuneratively employed, both to the benefit of themselves and the taxpayers; in fact, the citizens of San Francisco could better afford to maintain industrial establishments at a small percentage of loss, if by so doing they keep the deserving and industrious employed. And again, in view of conditions that exist in San Francisco, it shows a cruel indifference of the present wants of the people, and future prospects of the community, by encouraging importation of goods from the Eastern States and from foreign nations, to the distinct detriment and damage of our home industry.

The unhealthy condition of the average mind of this country, which looks with disdain upon manual labor, especially when it soils the hands or smuts the face, and the total disregard for the good of humanity in educating young men and women to thus regard labor, has overcrowded the professions, and proportionately degraded them. In the economic distribution of occupations but a small proportion can live by their wits; the great mass must now and in the future, as they have in the past, earn their living by the sweat of their brow. The skilled workmen in American workshops to-day are almost entirely foreigners, and to them is paid the higher compensation which should go to our own citizens.

Much has been done by philanthropic men in founding technical manual training and trade schools, but the aim has been too high for the benefit of the masses. Excellent superintendents, chemists, engineers and architects have been produced there, but the skilled mechanic, as such, has been almost entirely neglected. To reach such as are of mediocre talent, or not blessed with means, should be the main purpose of the manual training or trade school of the future; gather in and direct the physical energy of the young men and women so that, with the merest rudiments of a common school education, they can earn a living in an honest way, by the exercise of well-developed skill in some honorable handicraft, and educate the American-born mechanic to become the most skillful artisan among the artisans of the world. I believe the drift of opinion of those who are able to give and have seriously considered the situation as it really exists, is tending in that direction. James Lick, I think, in founding the California School of Mechanical Arts with \$540,000, and J. C. Wilmerding, who founded the Wilmerding School with \$400,000, had such an object in view. James Lick used these words in his will: "To educate males and females in the practical arts of life, such as workers in wood, iron and stone, or any of the metals, and in whatever industry intelligent skill now is or can hereafter be applied." And Mr. Wilmerding uses in his will the following language: "To teach boys trades fitting them to make a living with their hands with little study and plenty of work." The teaching of trades by school instruction confined to a particular trade, as in the old apprenticeship system, can scarcely be economic-

ally administered now, and a broader line of instruction is demanded by the modified conditions of industrial pursuits. Machinery has relieved the artisan of a great deal of mechanical labor, and such work capable of being done by a machine is unworthy the labor of man. The intelligent use of tools, tools being man's agent as man is God's agent, should be prized by every boy, and, in a limited way by every girl, and should be esteemed as a privilege. To teach the proper use of tools, so that such can be utilized in industrial pursuits, and can enable the artisan to make a living through his own labor, is the function of a trade school. The instruction here given to a pupil should have for its primary purposes the encouragement of industry, the means of making a living through some industrial pursuit, and the instillation of truth and honesty; and such instructions should be limited in the class room to the mere rudiments, but leading to the technical schools, by those who are competent and desire to go there, the technical schools bearing about the same relation to the trade school as the high school bears to the grammar; but the trade schools should admit pupils at as early an age as apprentices were indentured. It is probable that with three years, or four, grounding in the general use of tools, accompanied by necessary collateral class-room instructions, that the pupil should decide what calling he intends to follow, and then special instructions should be given in such calling, so as to fit him for the vocation he has chosen. Thorough, complete and concrete work should be done in the school; and if it is intended finally to launch the pupil into the world as an artisan, and not a jack-of-all trades, he is entitled to the same special instruction as a post-graduate or a collegiate taking a special course. The amount of good done by the manual training and technical schools cannot be fully recognized except by comparing the status to-day of the American engineer, among the engineers of the civilized world, with what it was thirty years ago; and it is to be hoped that within the next few years, in making the native American mechanic an artisan, he will occupy relatively the same proud position, and when it is remembered that the number of mechanics, as compared with the number of engineers, superintendents, etc., must be as thirty to one, it is a result most sincerely to be desired, both from the social and economic view.

The Nicaragua Canal.

There are many signs that the Nicaraguan canal project is growing in public favor. The popular feeling is manifest in the fact that scarcely any sort of public convention—political, social or other—is held nowadays without adopting resolutions calling upon the Government to take up the work and carry it out. All the political conventions of the year have so resolved; all the representative bodies of this coast have so resolved, and now social organizations like the Grange are joining in the movement. Senator Morgan of Alabama, the chief promoter of the project in the political world, has just made a report on the bill now before Congress, which puts the matter in the light of a simple business proposition. The present company, Mr. Morgan explains, has a valuable franchise and has expended several millions of dollars in preliminary work. If abandoned, this will be wasted or pass into foreign hands. The pending measure gives the Government absolute control of the canal, through ownership of seven-tenths of the stock. The work can be completed for less than \$90,000,000. Finished, it will earn enough at \$1 per ton charge on shipping (half the tolls on the Suez canal) \$4,000,000 per year, after paying operating expenses and interest on bonds. This is four per cent on the entire issue of stock, of which the United States will hold \$70,000,000. There is only one objection to this bill, namely: that it does not make the Government sole owner of the canal. There is no reason and there can be no possible advantage in a partnership arrangement with a private company even though the Government have a majority of the stock. It will only make a lot of "insiders" who will contrive ways to get contracts, etc., for their own advantage. The thing ought to be gotten wholly into the hands of the Government by fair and legitimate purchase of all interest or title, and then it should be promoted wholly as a national enterprise. There is, we are aware, some technical objection to nominal governmental ownership of the canal, but it is a mere lawyer's objection, without force in morals or in the spirit of things. In common sense there can be no objection to sole ownership that will not equally apply to seven-eighths ownership; and it is silly to quibble about it. The necessity for Government ownership is of a sort which must override outworn and obsolete laws and create new laws to fit the case.

The Government ought and must build the canal, and the conditions can never be more favorable than now. Money can be gotten at cheap rates; there are multitudes of men who need employment. As Senator Morgan puts

it, "inauguration of this work would be the greatest possible relief to the depressed and desperate laboring classes. It would benefit those who stay at home as well as those who go to Central America. It would relieve communities of the burden of care for thousands of unemployed, and put an end to the destructive competition for work which depresses wages and handicaps labor of every kind. No wiser measure in interest of the working classes could be conceived. If these understood their interest, mass meetings would agitate for the canal bill, and petitions would pour into Congress in its favor. It is a means of public relief as well as of national progress and commercial extension."

Lessening Demand for Horses.

The following is from an address by Hon. F. A. Derthick, Mantua, O., before the students of the Ohio State University:

The breeding of horses has heretofore been a profitable feature of agriculture, and its demoralization is no doubt an important contributor to the depression that is said to overshadow the vocation of the farmer. If our surplus horses could be disposed of, as in former times, it would relieve the stringency felt upon most farms, in two ways: First, by the money received for the horses, and, second, by the release of thousands of tons of hay and grain now held to feed to unprofitable stock. It is impossible, however, to dispose of any but the more desirable animals, and these at prices greatly reduced.

The Great Depression.—This change is due to several causes, among which can be numbered the general depression in business circles. There are, however, causes that will not be removed by a return of business prosperity. First, the quite general introduction of cable and electric cars within the past five years. Within this time the demand for horses for the street-car service has practically ceased. The influence of this alone can hardly be estimated. The life of the street-car horse was exhaustive and therefore brief, and to supply his place gave a steadiness to the horse market. The change in the motive power of street cars not only cut off the demand, but the thousands of horses already in use, now no longer needed, have found their way back into the country.

Electricity.—Nor is the end yet. The road commission appointed by the Governor last winter to investigate the subject of improving our public highways is quite likely to report adversely to the use of stone and gravel in the construction of free turnpikes on the more important roads. A part of the membership of this board is known to favor the use of steel rails. The plan is that important roads shall be traversed by electric cars, which will not only transport passengers at frequent intervals, but also with night trains haul produce to market. It would be folly to predict failure for this plan, for already suburban trains are run between adjoining cities, and roads are in process of construction in many parts of the State. There seems to be no limit to the skill and inventive genius of man, and the day may not be far distant when the services of horses may be dispensed with in ordinary country travel. It is insisted that it is not a question of possibility, but—"how soon" we shall be able to connect our individual trolley with the public electric wire and bowl across the country independent of horses. Who shall say that in the near future the young man, with his carriage equipped with a storage battery, may not go for a ride with his best girl, in which event the material for "a spark" would be an un-failing accompaniment?

Bicycles and Wings.—The advent of the bicycle has also contributed to the general slaughter of price and demand for horses. Large numbers of men and women who, until recently, kept a horse each, either for pleasure or business, have purchased a wheel and disposed of the horses. Again, I notice that on the 18th of November last, the first canal boat in the world to be propelled by electricity plowed the waters of the Erie canal. It is expected that at an expense of 50 cents per day per boat for electricity furnished by Niagara Falls, a boat will be sent from Buffalo to New York in much less time than at present, and with no outlay for driver, hay, oats or horseflesh. It would not be so bad if this were all. Did you notice the report of the international meeting of scientists held at Chicago during the World's Fair, and that they discussed in all seriousness the question of a flying machine? Ten years ago this body would have ridiculed the idea, but to-day these learned and dignified men declare, in all seeming sincerity, that the time is coming, and early too, when men will fly where and when they please, and from dizzy heights look down upon those of us who conduct ourselves with the snail-like pace of the old-fashioned horse. You will admit that a good part of this review recounts facts accomplished. A part, it is true, is speculation, but who dare say that is conversant with the development of the last decade, that it will not be realized in the decade to come?

The Production of Artificial Rain.

By B. S. Pague, Forecast Official U. S. Weather Bureau,
In arid or semi-arid regions the subject of rainfall in connection with crop production is a most important one. The question of what is the least amount of rain that is necessary to produce crops has been frequently argued, but this one fact can be relied upon: Good crops on other than adobe soil can be raised with ten inches of rainfall, if the rainfall is properly distributed and the temperature conditions favorable. With unfavorable temperature conditions at the time the stem of the product is full of sap, 40 inches of annual rainfall will not assure good crops. In California the autumn rains begin in October, and by December 1st the soil in all parts of the State is in condition to plow and seed. The rains of December, January and February are usually sufficient, even in the phenomenal dry years, to cause the seed to sprout and the grain to grow. Statistics bear out the assertion that it is upon the rainfall of March, April and May that the crops of California depend. The largest crop ever produced in the State was in 1880, when in April the rainfall was the heaviest on record. The years of great drouth in California and consequent short crops were in 1851, 1864 and 1877. As the State is developed the necessity for irrigation is more apparent, and more irrigation is practiced year by year, so that the same percentage of deficiency in the total product will not prevail that did prevail in former years of deficient rainfall. The following statement shows how the rainfall this season compares with the average:

PLACES.	Total for Season to date.	Average Seasonal to date.	Average Seasonal July 1 to June 30.	Percentage of Deficiency for Season to date.
San Francisco.....	16.10	20.88	23.93	23%
Red Bluff.....	19.15	22.23	26.66	13%
Sacramento.....	13.85	16.91	16.53	18%
Fresno.....	6.17	9.93	9.27	25%
Los Angeles.....	6.40	16.15	13.22	60%
San Diego.....	4.76	9.88	11.16	52%

In the season of 1876-77 the total rainfall at Los Angeles amounted to 5.28 inches, at San Francisco to 10.00 inches and at Sacramento 8.96 inches. In 1863-64 the total at San Francisco amounted to 10.08 inches, at Sacramento 7.87 inches, while for the least seasonal rainfall on record, in 1850-51, at San Francisco 7.40 inches and at Sacramento 4.71 inches fell. In a period of 45 years there have been three seasons of drouth in California, and in addition several years of markedly deficient rainfall when vegetation suffered and crops were short for lack of rainfall.

A popular fallacy exists that after all great battles heavy rain fell and that the rainfall was due to cannonading. This fallacy took such a strong hold of some that Congress was induced to make an appropriation to determine whether rain could be produced by the use of explosives. The experiments were conducted in 1891 in Texas, under the charge of the Forestry Division of the Agricultural Department. The official report on the subject, made by the meteorologist who accompanied the expedition, contained the following: "These experiments have not afforded any scientific standing in the theory that rain storms can be produced by concussion."

When the expedition reached Midland, Texas, some experiments were made to test the material composing the rackarock. No results were expected from the tests, but the following afternoon considerable rain fell. An employee of the expedition took upon himself the sending of the following message: "Fired some explosive yesterday afternoon; raining hard to-day." This first telegraphic report was followed by others. As the actual operation and result have become known, the attitude of the newspapers became changed from unsuspecting and ready acceptance to satire and ridicule. Where millions saw the dispatches, only hundreds have read a detailed account of the exact facts, and a vast number of people still believe that the experiments were in some degree successful, and that concussion, when made for the purpose, will produce rain. So errors which will require years of teaching to eradicate have been sown broadcast in a single summer, and the rain-making myth is added to the numerous errors about the weather which already prevail.

Rain-makers are now at work in this State, especially in those sections where the deficient rainfall is most noticeable in its effect on crops. Mr. Edgar B. Davison of Ballard, Santa Barbara county, writes this office under date of April 5, 1894: "Would you kindly inform me as to the possibilities of causing rain by artificial means. We all know that during the Harrison administration experiments were made on the production of rain, but the newspaper reports were so conflicting as to be entirely unsatisfactory. Were these experiments as complete failures as some authorities would have us think? We have the prospect of a dry season staring us in the face, and there is some talk of 'rain experiments.' Will you kindly give me your opinion on the matter?"

This is in answer to Mr. Davison's letter: For example,

suppose you take a cubic mile of air, upon which operations were made in Texas on the night of Friday, November 25, 1892. The record shows the temperature of the air as 72°; the dew point as 31°. To cool down a cubic mile of that air to the dew point would require the abstraction of as much heat as would raise 88,000 tons of water from the freezing point to the boiling point. To cool it down another 11° would require as much more heat to be abstracted. The amount of water set free would be 20,000 tons, which spread over a square mile would give about 1.4 pounds per

some divine power in this way cleanses the earth or that the vapor from the blood steams forth and makes moisture fall. If from a great heat a large body of air is made to ascend in a column, a large cloud will be generated and that cloud will contain in itself a self-sustaining power which may move from the place over which it has formed and cause the air over which it passes to rise up into it and thus form cloud and rain, until the rain may become more general. This is in theory, but the records of great fires do not show that rain has been caused by them. Relative to explosions

words, when the conditions are favorable for rain explosives and fires may precipitate rain, but when the air is too dry no artificial means can cause rain to fall. Legitimate scientific investigation for the production of rain should be encouraged, but the experiments should first be carried on in the physical laboratory before attempting them upon nature's great physical laboratory.

San Francisco, Cal., April 11, 1894.

AND NOW comes the "Prune Horse," which won the

THE PRUNE HORSE—A FEATURE OF THE SANTA CLARA EXHIBIT AT THE MIDWINTER FAIR.

square foot, or 0.27 of an inch of rainfall. The amount of latent heat set free by the condensation of that amount of water would raise 100,000 tons of water from the freezing point to the boiling point, and it would be necessary to abstract this heat in order that the rain-making might go on. The foregoing is on the presumption that the cubic mile of air be kept constant; if the air operated on is constantly changing, the task becomes one of infinitely greater difficulty.

Two causes of artificial rain have been suggested—explosion and fire. The belief that battles occasion rain is older than the invention of gunpowder, for Plutarch, in a sentence often quoted, says: "It is a matter of current observation that extraordinary rains pretty generally fall after great battles." And he explains this by supposing that

or concussions, it appears probable that on the southeast quadrant of a storm, the region of greatest moisture, if no rain should fall, though it threatened, that great concussions to cause a disturbance of the water particles held in suspension would produce rainfall. The Texas experiments were made without attempting to produce rain when the conditions were favorable for rain; but, under any and all conditions, the attempt was made, with the result a practical failure, though in a few instances a few drops of rain fell.

It may be stated in conclusion that, admitting that explosives and fires have in some few cases determined rainfall, they can only do so when moisture is present in sufficient quantity in the air, and when the other conditions, such as temperature and wind, are favorable. In other

first heat at Chicago, and is now in for the second at the Sunset City. This animal has doubtless surprised even his breeders in the way he gets over the ground of popularity. It is claimed that he did more to advertise the prune product of Santa Clara county at the World's Fair than any other more dignified display could have possibly done.

The prune horse was "one of the things to see" all through the Chicago season. So notable an affair should be seen in the Santa Clara building by all who go to the Midwinter Fair. The engraving gives the main points of his composition and environment. Horse and rider have consumed in construction 510 pounds of prunes and 80 pounds of other fruits. In his occasional grooming additional amounts are employed.

Mechanical Progress.

Compressed Air vs. Hydraulic Power.

After many years of experience the system of hydraulic transmission has been carried to a high degree of perfection, and the conditions of success are well understood. To transmit power economically and efficiently by water a very high pressure must be adopted, with a moderate velocity in the mains. This moderate velocity in the mains is dictated not only by considerations of friction, but also, more imperatively, by the necessity of limiting the stresses due to the inertia of the incompressible mass of water in the mains when the velocity changes. The whole mass of water in the mains must change velocity simultaneously, hence the shocks due to sudden changes of velocity are very serious. Both the high pressure and the low velocity limit the size of mains which can be used, and, therefore, the amount of power which can be transmitted.

Systems for transmitting power by compressed air are not yet so completely worked out, nor are the conditions of economy and efficiency so well understood. The unavoidable heating losses in compression limit the pressure which can be used in air transmission, and it is doubtful if in any case efficiencies quite so great as those attained with water can be realized with air. Nevertheless, there are cases where the moderate pressures used in air transmission are far more convenient than the high pressures required for water transmission, and there appears to be no definite limit to the size of the main which can be used or the amount of power which can be transmitted, if necessary, by air. For three reasons the velocity of flow in the mains may be very much greater with air than with water. The friction in the mains is less with air than with water in the ratio of their densities. The frictional work is less an evil with air than with water, because part of that frictional work is recoverable. Lastly, the elasticity and small density of the air make the danger of shocks or inertia stresses practically vanish. Water can only afford work less than the produce of its pressure and volume, but air used expansively gives an amount of work greater than the product of its pressure and volume; hence it turns out that with a given size of main a considerably greater amount of power can be transmitted with air of moderate pressure than with water of very great pressure.

Hardening Plaster.

The French, who have carried the art of hardening plaster to where it is utilized for flooring, either in place of wood or tile, use six parts of good quality of plaster intimately mixed with one part of freshly slacked lime, finely sifted. This mixture is then laid down as quickly as possible, care being taken that the trowel is not used on it for too long a time. The floor is then allowed to become very dry, and afterward thoroughly saturated with the sulphate of iron or zinc, the iron giving the strongest surface, the resistance to breakage being 20 times the strength of ordinary plaster. With sulphate of zinc the floor remains white, but when iron is used it becomes the color of rusted iron; but if linseed oil, boiled with litharge, be applied to the surface, it becomes of a beautiful mahogany color. Especially is this the case if a coat of copal varnish is added.

THE Chicago & Northwestern mechanical department is using a soda compound to soften the feed water, and it is reported to give very satisfactory results. The mixture is similar to that employed by the Chicago, Milwaukee & St. Paul, the recipe for which was prepared by Mr. George Gibbs, the mechanical engineer. The use of this mixture appears to be a very profitable investment, for it keeps the heating surface fairly clean,

reduces thereby the amount of boiler work to be done, keeps the engines longer in service between the periods of going in for repairs, and saves enough fuel to pay the expense of the compound.

A Strange Break.

At the Scranton shops of the Delaware, Lackawana and Western railroad there were recently made some tests of wire rope and fastenings for it. One and a half-inch steel cables are used in some of their mines, and these tests were made to determine whether or not the fastenings were as strong as the cables. Sockets with taper holes, known as rope cones, to receive the rope, and ending in a fork to fasten to the cage, are used. The rope is passed through the hole and the ends of the wires turned back, making a bushy head. Into this mass of twisted and doubled wire they pour lead or babbit metal.

The pieces are tested in their regular wheel press. It was soon proved that the rope was amply strong, sustaining 70 tons with no other effect than a reduction of diameter owing to the compression of the soft center. Lead proved very soft for fastening the wires—they pulled through it. A composition of three parts lead to one part antimony did far better.

The forks sustained load enough to bend steel pins two inches in diameter before breaking, but when they did break a curious thing happened—one side of the fork broke in two places, and a piece about an inch long dropped on the floor. This happened when the load was about 70 tons.

The cross section of the metal was the same where each break occurred—but why should two occur?

PAPER COGS for gearing have been proposed by an audacious inventor. They would be made in connection with sections of framework to go outside an iron wheel. Lightness would thus be secured, but, more than that, a certain elasticity where there is a sudden jerk of the shafting would result. In such emergencies iron cogs are sometimes stripped off and the machinery is paralyzed for days while waiting for repairs.

BESIDES having pneumatic tires for bicycles, they make pneumatic hubs in England. These are said to promise increased speed, although the invention is not yet perfect.

Mining an Underground Forest.

The working of a mine the product of which is timber is an operation not to be seen every day, but a noteworthy mine of this sort is to be seen in Tongking, where in a formation of sand, at a depth of from 14 to 20 feet, a deposit, tolerably thick, of the stems of trees, which, thousands of years ago, must have existed as an extensive forest, but eventually became buried by an earthquake or other similar phenomenon, and has been opened and is now being mined through gangways.

The timber in no way forms any kind of coal, but is in good condition, a fact to be attributed to the large proportion of resin which it contains, and the sandy nature of the ground in which it lies. The Chinese work the mine methodically, and use the timber chiefly for sculptural purposes, coffins, troughs, etc.

The stems have a diameter of a yard, are 45 feet long and appear to be a kind of fir very similar to pitch pine.

A BILL permitting the construction of an elevated electric railway between Washington and New York has been introduced in the House by Congressman Catchings, of Mississippi. It is designed to run trains at the rate of 150 miles an hour over this road. The company is to be capitalized at \$15,000,000, and the charge for transporting passengers is not to exceed two cents per mile.

Metallurgy and Ores.

SELBY SMELTING AND LEAD CO.

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

—AND—

ASSAY OFFICE.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurates.

—MANUFACTURERS OF—

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

—ALSO MANUFACTURERS OF—

Standard Shot - Gun Cartridges,

Under Chamberlain Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

68 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Smelters, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents of the Denver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$8.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

TUBBS CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice

611 & 613 Front St., San Francisco, Cal.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

DEWEY & CO., Patent Agents,

220 Market St., Elevator, 12 Front St., S. F. TELEPHONE NO. 658.

ACTUAL BUSINESS PRACTICE.

PACIFIC Business College,
320 POST ST. SAN FRANCISCO.

Rates of Tuition Very Moderate. Bookkeeping, Penmanship, Shorthand, Typewriting, English Branches, etc. Graduates aided in getting positions. Send for circulars. T. A. ROBINSON, Pres.

HEALD'S

BUSINESS COLLEGE.

24 POST STREET, SAN FRANCISCO. FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing, Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils. Our school has its graduates in every part of the State. SEND FOR CIRCULAR. E. P. HEALD, Pres. O. S. HALEY, Sec.

ALEX KELLER, MINERALOGIST,

704 Powell St., San Francisco, Cal.

A large variety of Mineral Specimens, large size or small to suit. See collection, three cases, in Placer County Mineral Exhibit at the Fair. Also all kinds of mineral resources and capital wanted to help develop them. First-class chances to invest. Postal or note to the above address will find a ready response.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes). Inserted in Dewey's paper binder, 50 cents additional per volume.

THE GRIFFIN MILL.

A perfect pulverizer of all refractory substances by either the wet or dry process. It works better and at less expense than any other Mill, and is conceded to be the only perfect pulverizing Mill Manufactured.

For FREE Illustrated Pamphlet address

BRADLEY FERTILIZER COMPANY,
92 State St., Boston, Mass.

Adamantine Shoes and Dies

—AND— CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill supplies.

Scientific Progress.

Scientific Uses of Liquid Air.

Prof. Dewar has been lecturing in London on the scientific uses of liquid air. It has to be prepared and preserved at a temperature of 200° below zero. He showed the substance in large quantities. In his improved methods it is not preserved in a liquid or solid state by its own evaporation, but by having the heat of surrounding bodies completely screened off. The liquid oxygen is placed in a vacuum jacket which is immersed in liquid oxygen contained in a second vacuum jacket and connected to an air pump. Convection is annihilated by a vacuum which must be all but absolute, and conduction is shut out by the surrounding oxygen, and radiation seems to be infinitesimally small. With such oxygen experiments can be made for the determination of its specific and latent heat. A definite mass of platinum can be lowered into the liquid, and the gas evolved is easily calculated, and the heat that becomes latent in converting the liquid into a gas is measured. One of the most interesting experiments is that which illustrates the difficulty of an electrical discharge where there is little or no ponderable matter. A bulb containing a mercury vacuum is plunged in liquid oxygen at 200° below zero, and the remaining mercury is condensed, after which an electrical discharge through the vacuum is possible only by enormously increasing the voltage, when the discharge assumes a totally different form, the diffused phosphorescence giving place to luminous streaks. It would seem, therefore, that after a certain degree of rarefaction has been attained, the gaseous molecules are no longer sufficient in number to act as carriers for an ordinary charge, while a more powerful one bridges the space only by the aid of the few that remain. The result almost justifies the presumption that ponderable matter is always necessary for the passage of electricity through space, but at the same time it opens up the question whether space can ever be wholly free of ponderable matter. If a certain amount of vapor be still given off by mercury at 140° below its freezing point, to what temperature below minus 274° must we suppose hydrogen to be cooled in order to insure that no residuum shall remain in the gaseous form? Another experiment showed that in extreme cold the metals have their cohesion greatly increased. It also appeared that a magnet which has not been super-saturated has its magnetic activity markedly increased by a reduction of temperature. This increase of cohesion and magnetic force at very low temperature is to be considered in relation to the disappearance of electrical resistance in pure metals.—N. Y. Independent.

Glaciation of Brazil.

One of the results of the lively interest which geologists just now take in glacial phenomena is a timely paper by Professor Branner on the supposed glaciation of Brazil, says Geo. F. Becker in *Cosmopolitan*. There is no known evidence which will bear close examination that there ever was any general glaciation in that torrid land, yet erratic boulders and glacial till are so closely simulated as temporarily to have deceived observers of the highest order of competency. These misleading phenomena are common in regions where glaciation has prevailed as well as in the tropics; and they deserve the closest attention, since in high latitudes the hypothesis of glacial origin is more likely to pass unchallenged than it is at the equator. Fairly homogeneous solid rocks, like granite, are usually intersected by cracks dividing the mass into blocks of varying sizes. If such rocks are exposed to the decomposing action of the weather, the smallest blocks disintegrate most rapidly, because their surfaces are greater in pro-

portion to their volume. As for the large blocks, their corners and edges yield more rapidly than their flatter surfaces for a very similar reason, viz., that the surface exposed per unit of volume is greatest at salient points. The result often is that a dike or boss of rock is reduced to a small number of isolated, rounded lumps which closely resemble erratics. This resemblance is not strange when one considers that in water-wearing also salient points are the first to suffer.

The masses of clay mixed with sub-angular stones, which were mistaken for glacial till in Brazil, Mr. Branner refers, no doubt correctly, to land-slides. Such land-slides sometimes, in northern latitudes at any rate, even simulate moraines when they happen to have dammed a ravine, and the mutual attrition of stones in a landslide adds to the deceptive resemblance. Now, glacial till is surface material which has been plowed up and worked over by the force of advancing ice, while land-slides consist of superficial earth and rock disturbed and mingled by the force of gravity. Thus the mechanical origin of each is extremely similar; there is no cause for wonder that they have sometimes been confounded, and the greatest care should be exercised in discriminating them in regions where either is geologically possible.

The Original Americans.

It is possible, according to recent scientific researches, that the people from whom, in the opinion of some investigators, the name of America was derived were originally inhabitants of the Polynesian Islands. Ages ago, it is believed, a nearly complete land connection existed between those islands and Central America, the Pacific ocean being at that time almost bridged with a chain of islands.

The tribe of Indians afterward known as the Ameriques are supposed, from certain remains, to have first taken possession of an island, Momotombito, near the western edge of Nicaragua, where they left some very interesting carvings and other tokens of their skill.

Afterward, according to the theory, a subsidence of the land occurred which drove them eastward until they came to the fertile slopes of the Amerique mountains, where their descendants are still to be found. It has been suggested that Vesputius got his pseudonym of "Amerigo" from the name of this tribe of Indians.

If all these things are true, it might be pointed out that even geological convulsions have played a part in the long series of events leading up, as if in obedience to a decree of Providence, to the naming of the new world, not Columbia, but America.

Aluminum for Flash Lights.

The use of aluminum as a substitute for magnesium for the production of flash light is growing in favor among photographers. Its chief advantages are its higher activity and its freedom from objectionable odors on ignition. The commercial aluminum bronze powder can be used if all the grease be removed by the application of heat. The consequence of allowing the grease to remain is that the powder adheres in lumps, and a large proportion of it escapes ignition when blown through the flame. Another advantage possessed by aluminum over magnesium is its resistance to oxidation when in fine powder. The mixture recommended by Prof. Glasenapp for photographic work is composed of: Aluminum powder, 21.7 parts by weight; sulphide of antimony, 13.8 parts by weight. In preparing the mixture the same precautions must be taken as with magnesium.

THE Dakota river, with an estimated length of 600 miles, is believed by many to be the longest unnavigable stream in the world.

Electric Progress.

Tesla's Experiments.

It is not all an extravagant statement to say that never before in the history of the world has there been a scientific discovery about which centered such magnificent dreams as there are being built up on certain recently discovered electrical principles. Among these the foremost must be given to the astounding discoveries of the young Servian genius, Nikola Tesla, which are so novel and so extraordinary that the most imaginative of inventors are unable to foresee what form their development will take. Just as experimenters were beginning to think that they knew all that could be learned about electricity, and that further improvements must be in the line of more perfect mechanical application, Mr. Tesla shows us the electric fluid under conditions in which it differs from ordinary electricity as much as light differs from heat. A current of 2000 volts will kill a man in the twinkling of an eye, but this modern wizard lets currents pour through his hands with a potential of 200,000 volts, vibrating a million times a second and showering from him in dazzling streams of light. For some time after the experiment ceases his body and clothing emit streams and halos of splintered light.

The wildest dream of the inventor could not have foreseen that while currents of low frequency are deadly, these are harmless. Mr. Tesla says that he will soon be able to wrap himself in a complete sheet of electric fire that will keep a man warm at the North Pole without harming him. Neither Merlin nor Michael Scott nor any of the wizards of old ever wrought a more potent miracle, even in fancy. The meaning of this is too far beyond us to be realized at present. We can no more grasp the significance than Franklin could discern the electric motor in his captured thunderbolt. Equally astounding and with more visible usefulness is Mr. Tesla's discovery that currents of such enormous potential and frequency can be transmitted without the use of wires. A room can be filled with electricity from copper plates in ceiling and floor, so that the electric lamps will burn without any connecting wire as soon as they are brought in. In the same way intelligence and power may be transmitted without a circuit, doing away with necessity of trolleys, storage batteries and subways. When it is considered that such startling changes as this are already theoretically possible, it will be seen that in the inventions upon which we so complacently congratulate ourselves we have only just timidly paddled along the shore of the great sea yet to be explored.

Telephones for Local Uses.

The expiration, on January 30th, of the patent on the Bell metallic diaphragm telephone has developed a new field of usefulness for the telephone, and perhaps will entirely displace the speaking tube and electric bell annunciator. The cost of telephones for hotels and houses will probably not greatly exceed, if, indeed, they will not be cheaper, than the cost of speaking tubes or an electric annunciator service, while their convenience will be immensely greater. While the monopoly of the transmitter and switch-board devices, says the *Electrical World*, will prevent the residents of large cities from obtaining much benefit from the expiration of the patent referred to, farmers and residents of small towns, on the other hand, will obtain full advantage. They will be enabled to run short lines to their stables, places of business, or elsewhere, and in small towns it would seem to be possible to also have exchanges, as the necessary devices will be simple, and can be selected and used so as to avoid switch-board patents. In fact, several such exchange

systems are already in a state to put on the market with guarantees that they constitute no infringement on existing patents. There will be no scarcity of instruments, as, besides the firms who have prepared for that contingency, there are great numbers of telephones made for companies that were afterward declared infringers, and which have been stored to await the opportunity to place them on the market.

Coal Used in Producing Electricity.

The National Electric Light Association is making endeavors to determine the amount of coal used in actual practice in the United States to produce a given quantity of electricity. At a recent meeting of the association in Washington, D. C., some data which was procured through correspondence was presented. In this data the number of amperes, volts and hours on each circuit was considered in connection with the actual amount of coal consumed during the same period of time, including that used for banking fires. In this way the actual number of watt hours per pound of coal was arrived at in each case.

The results were at wide variance, but the rest of them cannot be said to compare very favorably with the results which have been reached in the generation of power for manufacturing purposes. The average of watt hours per pound of coal was found to be 91.7. The most satisfactory result was that in a large station generating about 8,000,000 watts and running 24 hours per day, which gave 208 watt hours per pound of hard screenings, while the opposite extreme was reached in the case of a station which claimed only 30 watt hours per pound of soft coal, the output being 30,000 watts and the service seven hours per day.

For purpose of comparison, experiments were made with the engines in a large manufactory in Brooklyn, N. Y. Upon these engines a load varying from 495 to 765 indicated horse power, averaging 653.3 horse power, was maintained with a coal consumption of 1482 pounds per indicated horse power per hour. The equipment consisted of Corliss compound condensing engines and vertical tubular boilers, which were in operation ten hours per day. The fuel used was George's Creek bituminous coal. The efficiency of this plant, therefore, is nearly double that of the best electric plant reported and about 13 times that of the worst one.

THE Koenigsberg Electricity Works is a station which is of considerable interest among German stations, and is remarkable chiefly for two features; its circuits are on the five wire system, and the mains are laid in conduits. The engines are of triple-expansion vertical type, and by Schichau of Elbing. There are two of 200-horse power and two of 100-horse power; they run at 200 revolutions a minute, and are directly coupled each to two multipolar dynamos, which have the outside wires of their disc armatures arranged as commutators. Very full descriptions are given in the columns of a German electrical journal of the circuits of the five-wire supply and also of the conduit in which the five conductors of bare copper strip are carried on insulators of the telegraph type. These mains are calculated for 60,000 lamps, but the present station can only supply 16,000. All details given are very full, and the financial results, in spite of the disproportionately heavy outlay on mains, are stated to be satisfactory.

THE original 1858 cable weighed 93 pounds per mile, and had a conductor of seven copper wires of 22½ gauge. Price of deep sea wire per mile, \$200; price of spun yarn and iron wire per mile, \$265; cost of outside coating of tar and gutta percha, \$25 per mile; total cost per mile, \$485. At \$485 per mile, the total cost of the 2500 miles of deep sea wire was \$1,212,500. To

this add 25 miles of "shore-end" wire, costing \$1450 per mile, and we find that the first ocean cable, exclusive of instruments, cost \$1,250,000.

Electric Wire Perils.

I believe that the peril from electricity in all its varied applications is diminishing, in consequence of the rapid increase of knowledge of the subject. The greatest danger results from the fact that most people are ignorant of its powers and the proper safeguards. This ignorance, at the same time, causes them to be unnecessarily alarmed. Another important element of danger from this force is that its effects are instantaneous, and that there is no means of warning before any given trouble occurs.

In the case of being burned, for example, heat is usually felt before the burning point is reached; but this is not the case with electricity. The safeguards against all electrical accidents, on the other hand, are extremely simple and reliable, and I believe that in a few years the subject will be so thoroughly understood by every one that electricity will be much safer and more easily handled by all than any other force.

There is an erroneous popular impression that many fires are caused by electric-light wires, but the statistics show that this is not the case; but, on the contrary, fires from electric-light wires are very rare. It is at present the custom to ascribe all fires in buildings where there are any wires to electricity, without regard to any evidence to show that the fire was so caused.

In regard to the recent alleged case of hysterical blindness, I believe that it is purely a "fake."—Dr. Schuyler S. Wheeler.

ON one of the Canadian lakes there is the only electrically driven sleigh in the world. The driver sits on a motor that works a couple of steel paddle wheels, and guides with a couple of rudders extending out and engaging in the ice behind.

Practical Information.

Pay Attention.

Whatever you are about, pay attention to it. Keep your mind on what you are at. Think of what you are doing. Close attention is very much a matter of habit; and it is a habit which should be diligently cultivated.

Take, for instance, the habit of mind in reading. One law student has a general idea that he has seen a case reported somewhere, in which he rather believes a certain point arose—he is not quite sure of that—which was decided one way or the other, he don't remember which! Another student, who had the same book in his hand the same length of time, remembers what reports it was in, the number of the volume, the name of the case, the names of the counsel, the points that came up, the views of the different judges, if there was a conflict of opinion upon them, and precisely what the decision was. He even remembers the part of the book, the very number of the page where it is to be found. In his mind's eye he can see the lines, the words, the letters. He has the habit of fixed attention, which all students should strive to acquire.

The opposite extreme of loose reading and listening is illustrated by some amusing anecdotes. One is of a man who said he had recently read in some paper, he couldn't remember where it was, of a man named Johnson—he believed his name was Johnson—who had raised a thousand barrels of potatoes to the acre—he believed it was barrels, it might possibly have been bushels; he was quite sure it was potatoes, thought possibly it might have been apples; it seemed a good deal for an acre, he might be mistaken about that—really it was impossible, it must have been more than an acre!

Another is of an old woman who said she

had learned a sure way to tell whether an egg was good or not; she had heard of a great many before, but this was certain, and it was so simple, too; it was to just drop the egg into a pail of water, and if it was good it would—either sink or swim, she really had forgotten which.

It is a very good practice after laying a book down to take up a pen and see how much you can write of what you have read. After trying it regularly for a week you will be pleased to find how much more you can remember than you could at first, so rapidly does the habit of concentrating one's thoughts grow with cultivation.

Think of what you are doing and you will remember what you have done. Cultivate the habit of keeping wide awake and of fixing your attention closely.

Bartissol's Panama Canal Scheme.

There does not appear to be any prospect that work on the Panama canal will be resumed very soon; but two or three features of M. Bartissol's scheme for finishing that famous job, as described in *La Revue Technique*, are interesting from an engineering point of view, and deserve mention. The old plan contemplates several levels and from eight to ten locks, between 122 and 175 feet above the sea. But M. Bartissol would get along with four locks, two at each end of a central level only 75 feet above the ocean.

As will quickly be perceived, this change of programme involves an increased amount of rock and soil cutting. The most ingenious part of the new scheme provides for the disposition of the extra material thus excavated. Beside the canal, and running down into the Pacific, he would construct a 12-foot tunnel, nearly six miles (33,000 feet) long, through which the debris would be washed. Water for this purpose would be brought through an open channel from a dam on the Chagres river. The projector would allow about one foot fall to every 1000 feet of length, and have his current fill the tunnel to a height of about ten feet. A flow of ten feet per second, it is estimated, would be secured, and this would discharge 1,000,000 cubic meters daily. A hundred shafts, cut into this tunnel, would empty into it only about 40,000 cubic meters of solid masonry in 24 hours, according to M. Bartissol; so that only about four per cent of the discharged mixture would be earth or stone.

This method of removing debris has been tried, on a much smaller scale, at the isthmus and elsewhere; but enough is known to give the engineer who proposes this 13-foot conduit confidence in its feasibility. Four years of time and \$100,000,000 of money are all that is required, he thinks, to complete the work on the foregoing basis.

Two Projects.

There are two projects for the Simplon tunnel on the Jura-Simplon Railway. One of these, by M. Lommel, provides for a double line through the tunnel to horings to be undertaken at a height of 2200 feet above the level of the sea. The tunnel will be 11½ miles in length, and the cost is calculated at about £4,300,000. According to the second plan, the tunnel would be made at a somewhat lower level, and there would be only one line of rails. This would reduce the cost to about half of the amount mentioned, and the tunnel, it is calculated, could be completed in 5½ years. Both plans suffer from the drawback that there will be a rapid fall on the Italian side, about 1 in 42. It has been proposed to construct a shaft 1800 feet deep in the interior of the mountain to secure better conditions of temperature. The latter is an important point, as it is expected that the temperature in the interior of the mountain will be as much as 95 degrees Fahrenheit.

An Eastern Opinion.

The *Railway World*, published in Philadelphia, is one of the prominent Eastern journals that, in discussing the free-coinage question, shows that a good deal depends upon the point of view. In its issue of the 14th inst., in a long article on silver and current politics, it says:

Many Congressmen and not a few Senators who favor tariff reduction on merely partisan grounds are sincerely and enthusiastically in favor of silver. They will support a tariff bill if the leaders commit the party to such a measure, but care little about the tariff, and would, it may be, prefer that duty on local products should remain undisturbed. They are warmly in favor of silver as money, and their constituents believe that such money is a necessary step to the return of prosperity. On the other hand, there is a powerful gold influence strongly entrenched along the Atlantic seaboard. Extreme silver men insist that the President and those closely allied to him are gold monometallists. A controversy on this subject might enliven many days. With here and there a struggle over a nomination, it might be protracted until the majority was divided into wings irreconcilably hostile to each other. It might become patent to all men that the tariff bill could not pass without a free-coinage amendment. The attitude of the President leads one to suppose that he would rather see the existing law remain on the statute books than give his sanction to any free-coinage movement. Here is a chance of killing the bill, either by tacking it to death, or so amending it that the President will be constrained to return it without his approval.

It may, therefore, be anticipated that a silver discussion will be encouraged by protectionists who do not wish to see free coinage adopted. One may go further. If the only way to defeat tariff smashing is to pass a free-silver bill, let us have free silver. Of the alternatives, the latter is far preferable. Last summer brought countless assurances that the repeal of the purchase clause would be followed by a great wave of returning prosperity. The purchase clause was repealed, but the depression continued, and in some lines even intensified. Business was affected by the dread of tariff reduction. Factories closed because they had no orders. Purchasers held aloof because they might be able to buy at lower rates under a new tariff. Miners found that the demand for coal had slackened because industrial establishments were silent or running on half time. Railways did not order new cars because many of their old ones were idle, nor did they engage new employees when train hands after years of faithful service were necessarily dropped from the payroll. The knowledge that the Wilson bill had passed the lower branch of Congress, and that it found defections in the upper house, increased the dissatisfaction felt in business circles everywhere. Granting that the silver-purchase clause was objectionable, and that it should have been repealed, it was a molehill and tariff agitation was a mountain. If Wilson and his committee had been treated as they deserved—that is, if no member had spoken of the bill except in terms of bitterest contempt, and if the hybrid had been voted down by an overwhelming storm of votes—business would have revived long ago. The country can far better afford to buy a specified quantity of silver than it can afford to place its manufacturing interests in the hands of men who know nothing about them and slam the door when people of common sense endeavor to teach them something.

Nobody can reasonably argue that our present troubles are due to the silver-purchase clause or to the fact that silver dollars are in circulation. European financiers long wedded to the gold standard are beginning to investigate the subject. Great Britain and Germany are willing to admit

Catalogues on Request.

that a bimetallic system is a possibility. Further concessions may be obtained. The use of silver as money far antedates what we call civilization, and the experience of ages is not to be discarded lightly. In many sections, gold coin is generally hoarded as soon as received, while the much-abused silver coin is kept in general circulation. A conviction that silver, as a great American interest, and as a precious metal from the days of Abraham to our own, demands recognition is certainly deeply rooted. The minority party in the United States Senate is as a unit in opposition to radical tariff legislation. Both parties have many friends of the white metal in their ranks. A bimetallic movement of some kind is to be anticipated. One may oppose free coinage, and yet hold that it is far less objectionable than a tariff which deprives us of protection and does not furnish revenue. If the people must choose between tariff smashing and free silver, it is to be hoped that the result will be free silver.

A New Gold Saving Process.

It is reported that an expert chemist at Denver is now successfully taking out 90 per cent of the assay value of gold from the various ores of Colorado and elsewhere. Capitalists and mine-owners are showing a deep interest in the practical development of his process, and the mining world at large will gladly hail any new chemical means of extraction from base or low-grade ore pulps which can be accomplished economically. A few years hence it is possible that the supply of gold will far exceed silver and that chemistry will solve the great problem, mechanism having reached its ultimatum of extraction.—Virginia Enterprise.

From South Africa.

A letter from the Witwatersrand (South Africa) says: "In coming here one has to pay 4d per pound for all excess luggage over 50 pounds second class, or 25 pounds third class; second class is £8, third class £4 8s rod, and no sleeping accommodation in the latter. That is in the train after arrival at the Cape. One has to pay 6s 6d twice on revolvers, and a guinea twice on gun or rifle per barrel. This is a black man's country; all labor or menial work is done by them. Smallpox and fever are the prevailing sicknesses. There are 30,000 black men employed on the mines, and only a few white men at each mine. There are some miners conducting the work of Kaffirs, and some are driving rock drills with two Kaffir boys as helpers. Tell miners they had better learn the use of the rock drill if they think of coming here, for without that knowledge they're not much use. For bossing boys £4 10s per week is the pay; then you want at least a slight knowledge of Kaffir lingo, and that is no joke to acquire. Machine men get £1 per shift when on wages, but it is nearly all contract work. I walked three weeks along the line of reef looking for work, and now I have got it I have scarcely cleared my tucker bill as yet, which is 27s per week. On the other hand, my mate makes 25s per shift. We have to pay a poll tax of 18s a year, and no vote or voice in the election unless resident for 15 years."

A Fortune in a Tin Roof.

Three thousand dollars for an old tin roof would be a pretty steep price, but the man who gets the battered roof from the old Tabernacle church, Broad street and South Penn square, Philadelphia, which is now being torn away, for that sum will be in great luck. Some years ago the paint was scraped off the old roof and yielded \$5000 in fine gold. It is almost as certain to yield as much this time. The gold comes from the United States Mint chimney, which is near by.

When gold is being coined, a considerable quantity of it volatilizes with the smoke through the chimney, and as soon as it strikes the air it falls. Much of it strikes the roof of the Mint—so much that the officials save even the water that falls upon it during a shower. All the drains from the roof are connected with large vats in the cellar of the Mint. Before the water finally gets to the sewer it is strained through many blankets and sieves, which retain the gold.

SENSITIZED postal cards for the use of tourists and other photographers are made in Germany. Therewith one can easily make prints to send by mail from negatives secured while traveling.

GIANT POWDER FUSE CAP FASTENER.

The instrument represented in the above cut is a new and grand little invention; being designed to save life and limb, and innumerable law suits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The instrument crimps the cap on the end of the fuse, firmly and absolutely water tight. There is also a Fuse Outter attached. They are neatly gotten up of the finest cast steel and nickel plated. Price \$1.50 each. MOODEY & SHERWOOD, Fresno, Cal.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also serve very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

MINI BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x86 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

AMADOR NOTES.—*Ledger:* The Bellwether mine, the property of S. W. Bright was last week bonded to a capitalist from Montana for \$125,000 with the agreement that a prospecting mill of ten stamps will be erected upon the property within 90 days, and that 60 stamps more will be added in 18 months. The man who bonded the property left Jackson upon securing the bond to consult with his partner in the enterprise, but before leaving put some men at work upon the property in charge of J. DiVecchio to get things in readiness for the hoist and mill which he designs to construct forthwith.

The people of Jackson are delighted with the condition of affairs at the Hardenburg. During the past few weeks they opened up a ledge which the outside people aver will go \$40 a ton. It is of such size that additional stamps are contemplated. Two concentrators have been put in during the past week. Upon his last trip to the mine, C. D. Lane of Angels looked over the ground very carefully with the idea in view of locating a new shaft. A new hoisting plant has been constructed, and, if a new shaft is sunk, will be placed over it, instead of at the old shaft.

An effort was made about a year ago to resuscitate the Good Hope mine, but the stringency of the money market at that time, and the tenacity with which the chief owner, Chas. Peters, held on to the control of the property, made it impossible to effect that, and the matter was practically dropped. Mr. Peters has concluded to make another effort at resuming work in that mine, and upon conditions that are more liberal than he has ever before offered. The Good Hope Company, of which he owns most of the stock, will sell 25 per cent of the shares at \$1 per share, to be paid in monthly installments, the purchasers of these shares to be allowed the privilege of purchasing as many shares as will place the control in the hands of the new members of the company. The president of the company, Robert Aitken, has in preparation a prospectus, which will be circulated in a few days.

I. N. Dewitt is in charge of a gang of men who for a little more than a week have been working upon the tribute plan at the Amador Queen mine. This is the same property which a few weeks ago was worked by a number of men in charge of John Fox, and who disagreed and quit the work after running the mill about a week. At that milling they got about \$10 per ton in free gold. The present force is chiefly busy with reopening and getting ready to start up in good condition; still, they have already taken out about 50 tons of rock. The force now consists of Dewitt, a blacksmith and five other men. The tunnel in which they are at work is 1200 feet into the hill, with an upraise of 175 feet. They will start up in a short time with 10 stamps, the power coming from the Blue Lakes ditch, from which they get 350 feet pressure.

EXTENSIVE WORK.—*Record:* The most extensive property under the control of one corporation in Amador county is now held by the Mayflower Mining Company, at Amador City. It extends from Rancheria creek to the north line of the famous Keystone mine, and includes such well-known properties as the Bunker Hill, Mayflower and South Mayflower, the Little Amador and Kling mines, covering an area of near 5000 feet in length with a width varying from 300 to 600 feet.

Near the north end of the properties is located the splendid 40-stamp mill and hoisting works of the old Bunker Hill mine, in which region and on the adjoining Mayflower ground the most of the present development work is being done. Some 80 men are now employed, and 20 stamps are crushing the rock being raised. It is expected that the additional 20 stamps of the mill will soon be at work crushing the output of this part of the property. The company is making preparations to reopen what is known as the Johns shaft on the south side of the ridge near Amador City, on, we believe, the Little Amador property. This shaft was originally sunk to the depth of 700 feet. When cleaned out and repaired development work and further sinking will begin from that point. Knight & Co. of Sutter Creek are now figuring on a hoisting and pumping plant for use at this shaft. As soon as developments will warrant, a new 40-stamp mill with all modern improvements will also be erected.

Dr. Stephen H. Emmons, general manager and one of the heaviest stockholders in the Mayflower Company, has been in this vicinity for ten days past overlooking the work in hand. The doctor was accompanied by his son. Both returned to San Francisco yesterday.

Every indication points to the fact that this company will soon be employing a largely increased force of men. They have the ground necessary, and all of it is located in what has long been known as among the most desirable and richest properties on the famed mother lode.

Butte.

A MINING BOAT.—The Oroville *Mercury* describes the mining boat constructed by the Kansas City Dredge Co., at that place, as a substantial structure about 65 feet long, with an upper and lower deck and a hold. The machinery for raising the gravel consists of a dredger apparatus, of steel scoop buckets arranged on an endless chain. These dip into the bed of the river or the bed of gravel pro-

posed to be worked, and scoop up the earth, carrying it up to an elevated drum screen. There it is dumped and played upon by a stream of water pumped from below. As the screen revolves, the heavy gravel is thrown off, while the smaller gravel falls through the drum into an amalgamator, worked backward and forward with relatively the same motion as the old "long tom." When the heavy gravel is thrown off, it passes by means of an endless belt out over the boat to the river. After the gravel goes from the screen into the amalgamator, it is thoroughly amalgamated and passes out into a line of sluices equipped with Hungarian rifles, where the residue of gold is caught, thence out over the stern of the boat to the river. A 40-horse power engine runs all the machinery. The boat will be moved up and down the river from place to place by means of guy ropes from the shore. It is expected that it will be in action in about ten days or two weeks. The owners have expended a large sum in constructing the machine and have leased all the lands adjacent to the river.

Calaveras.

Osa Staike at Angels.—*Angels Echo:* A rich strike has recently been made in the Blair mine, near Smith's Flat. The rich discovery was made on the 200 level, where the vein is over 12 feet in width. The Blair mine is a splendid piece of property and gets richer as depth is attained. We understand that it is the intention of the owners to sink the shaft 100 feet deeper. When this mine is thoroughly developed it will be second to very few mines in this county as a gold-producer. It is said that \$46,000 was taken out of the Blair mine in a single day recently.

El Dorado.

SUMMIT FLAT'S BOOM.—Considerable stir is reported from Summit Flat, El Dorado county. The Granite and Unity mines are increasing their forces and pushing work day and night. Supt. Cummings of the Granite has leased the Rodgers mill, which he has repaired and put in first-class condition for the reduction of cement gravel. The Murdoch Bros. are vigorously prosecuting work at their Negro Flat claim. Col. Root has completed and is now running his five-stamp mill at the Ralph gravel mine, with a decidedly promising outlook. The Snow Bros. are about ready to start up their mine. Anton Bentler has got in a supply of timbers and commenced work on the old Union mine, which was famous in former years for its immense yield of gold. At the Texas Hill mine they are running a tunnel, and are now within 400 feet of the famous old Prospect Flat mine. Dr. W. W. Stone will immediately erect a five-stamp mill on the old Ignac mine, where they have recently struck a rich bed of cement.

Nevada.

MINAS' WADES.—There was great excitement in town last night for half an hour or so, says the Grass Valley *Union* of the 24th, when 13 or 14 carmen and landers came in from the Maryland mine looking for Supt. Dorsey. A notice had been posted at the mine that wages of carmen in future would be \$2.50 per day and landers \$2.75. Under the Idaho management the wages had never been less than \$3 for such workmen; and while the men were peaceable, they were determined to work for no less than the standard scale. Asst. Supt. Victor Dorsey, after listening to the men's grievances, informed all who left their work that they could return to work at \$3 per day, and this morning everything will move along as though nothing had happened.

LATO OFF.—*Herald:* When the day shift at the Harmony mine knocked off on Saturday evening, the miners—14 in all—were notified that their services were no longer required. Four men on the night shift were also "given their time," making 18 in all. Supt. Gowell assigned no reason for the draft, and the men asked for none. They take it that he discharged them merely from personal dislike as a result of the recent strike.

THE RAINBOW MINE.—*Herald:* The Rainbow mine, near Washington, is to be started up at once. It has been prospected for a year and a half, a whole year of which was spent in running a tunnel. Last fall the ledge was struck, and then Superintendent Garland closed down for the winter. Mr. Garland returned to the mine lately, taking several men from Nevada City. The Rainbow mine is a big proposition, and we shall hear from it this summer.

THE GOLD FLAT MINE.—The owners of the Gold Flat mine met recently in Grass Valley and decided to erect a five-stamp mill on the property for the present and in a short time more stamps will be put up. Dave Muir of Nevada City will build the mill.

Last Sunday a rich strike was made at the Eagle Bird mine, in Washington district, says the Nevada City *Transcript*. The ledge, as far as cut into, is 12 feet wide, and there is no telling how much wider it is. Some of the quartz shows free gold.

San Bernardino.

Red Rock PLORES.—The placer mines at Red Rock, 38 miles northeast of Mojave, are attracting considerable attention. They were discovered by a Mexican March 30th. It is reported that men are making from \$3 to \$5 per day. Men are coming in fast and taking up the best claims. Claims that will pay from \$3 to \$15 per day per man are sold from \$100 to \$1500.

A GOON CAMP.—*Kern Californian:* Summit mining district, out on the Mojave desert, is having a big boom. There are over 200 men permanent residents of the camp, and 60 dry washers are constantly at work. Curiously enough, the flat mesa lands pay better than the gulches, and the ground yields more gold right at the surface than it does deeper down. No

bedrock has been struck yet in this district, but at from 4 to 12 feet from the surface there is a layer of cemented clay where most of the mines stop, although the dirt below this will pay wages if worked. The gold from this district is worth \$18 an ounce, or from 50 to 60 cents per ounce more than the Red Rock and Goler gold. Every dry washer is working on pay dirt. The highest product lately has been an ounce and a quarter in a day, but an ounce of gold to the machine is the regular thing.

PLACER LOCATIONS.—*Mojave Miner:* Many placer locations have been made in the Burro creek country and it is said some of them are very valuable. The gold is coarse and easily saved. Men who are out of employment can make good wages working these claims, as wood and water are handy.

Siskiyou.

MINING NOTES.—*Yreka Journal:* R. S. Taylor brought to town last Friday about \$125 in coarse gold dust, taken from the head of Horse creek, a tributary of the Klamath, which was panned out in three or four days, by the party making the strike. The same person then cut through the rim into the gravel about 60 feet above and found still richer prospects, averaging from \$5 to \$15 per square yard of gravel washed in a pan.

Austin & Co. of the Greenhorn blue gravel mine, about a mile south of Yreka, still continue to take out good pay, or about \$900 a week. The yield has not varied from this amount to the extent of \$20 a week for six weeks past.

Although the above mines are called blue gravel beds, there does not seem to be any blue gravel where now worked. At the original shaft, first sunk down near Lee's house, the gravel was of a bluish, cement-like character, but the aniferous gravel now taken out is yellow, and fully as rich as the blue. There is no doubt that a vast area of this rich gravel, over 100 feet below the surface, on Greenhorn creek and throughout Yreka basin which is likely to be developed in course of time.

Trinity.

GOING AHEAD.—*Journal:* Water is running through the La Grange Hydraulic Mining Company's ditch to the mine, with the exception of about three miles at the head, where the snow is very deep and there are some slides not yet cleared out. It was turned through the pipe lines last Monday. At present about 800 inches of water are delivered at the mine. The Coal creek water will soon be turned in, increasing the supply by 300 or 400 inches. The mine now has a better water supply than ever before.

NEVADA.

Washoe District.

ON THE COMSTOCK.—*Enterprise:* The south drift from the top of the raise above the 1000 level of the Consolidated California & Virginia is showing more favorable in the face as the shaft is advanced.

The Alta mine has above 250 tons of ore on hand, extracted from the various openings in the vicinity of the 725 level. The average assay value of this ore, by car sample, is about \$35 per ton. The mill is in first-class order, and will be started up in about ten days. The official letter from Colonel Boyle, detailing operations the current week, shows that gold predominates over silver in the ore extracted in a ratio of three-fourths of the former to one-fourth of the latter.

Following are the official letters of superintendents detailing operations in the Comstock mines the current week.

CON. CAL. & VIRGINIA.—On the 1650 level the drift running north from the end of east crosscut No. 1 run from the north drift from the winze—down 52 feet—has been extended during the week 10 feet; total length, 136 feet. From this drift north, at a point 126 feet in from its mouth, an east crosscut was started and has been advanced ten feet in porphyry and streaks of quartz of low assay value. At a point 120 feet south from the winze and 20 feet below the sill floor of this level (1650 level), we cut through six feet of ore. In stopping out upward on this ore body we have extracted during the week 35 carloads of ore, the average assay value of which is \$76.70 per ton.

1000 level (the Rule drift).—The drift running south, from the upraise, 50 feet was carried up at a point 353 feet south from the shaft station, on the east crosscut, has been extended 42 feet, and from this east crosscut, at a point 180 feet in from its mouth, a south drift has been advanced 16 feet in some vein matter carrying a low assay value.

At a point 477 feet south from the shaft station a west crosscut—No. 2—has been advanced 30 feet in vein matter. At a point 590 feet south from the shaft station a west crosscut—No. 3—has been advanced 30 feet in porphyry and quartz.

ANDES—420 level.—The upraise started in the west crosscut No. 1 from the main north lateral drift was carried up 12 feet during the week, continuing in quartz.

UNION MINE—900 level.—The Union Con. and Sierra Nevada joint east crosscut near the north line of the Union mine, running from the joint west drift, at a point 1520 feet west of shaft, has been extended during the week 15 feet; total length, 248 feet; face in hard porphyry.

OPHIE—1465 level.—The drift running south from the drift run west from the main north drift, at a point 219 feet in from the mouth of the creosote, has been extended during the week 19 feet; total length 44 feet, continuing in porphyry showing lines of quartz.

As joint work with the Mexican Company, repairs have been made in the main shaft at and near the 700-level station.

Central Tunnel.—The north drift from the main west drift has been reopened and repaired during the week 26 feet; total length reopened

303 feet, and it has reached the north end of the old Mexican shaft station.

MEXICAN—1465 level.—The upraise started near the mouth of the crosscut run west from the drift run south from the top of the upraise, which was carried up 45 feet above the sill floor of this level at a point 40 feet from the main north drift and 100 feet north from the south line of the mine, has been carried up during the week eight feet; total height, 74 feet; continuing in a very hard porphyry formation.

As joint work with the Ophir Company, repairs have been made during the week in the Ophir shaft at and near the 700-level station.

BAST & BALCHRA.—On the 900 level during the past week the main north drift has been cleaned and repaired a distance of 160 feet; total length, 320 feet.

GOULD & CUNAY.—On the 200 level west crosscut No. 5, started in the northwest drift, 432 feet from the main west drift, has been extended 18 feet; total length, 1028 feet; face in porphyry.

HALA & NORCROSA—900 level.—Advanced the south drift 10 feet; total length, 192 feet; face in porphyry.

1100 level.—Advanced the main south drift 21 feet; total length, 193 feet; face in porphyry.

WEST CON. VA. & CAL.—During the past week the west crosscut on the 1100 level, run from a point 320 feet north of the shaft station, has been extended 26 feet, and is now in a total distance of 705 feet. Face in hard quartzite, with slight indications of a change of material. The flow of water has somewhat decreased since the last report.

SAVANA.—On the 1050 level the north drift from the station was advanced 28 feet, making its total length 58 feet. The west crosscut from southeast drift, started 225 feet from the shaft, was advanced 6 feet; total length, 47 feet; face in quartz and porphyry. The south drift was advanced 22 feet, making the total length 177 feet from the shaft. On the 1100 level the north drift from the shaft was advanced 15 feet; total length, 152 feet; face in porphyry.

On the 12th floor they are extracting some pay ore.

During the week they hoisted 30 cars of ore from the 1050 and 1100 levels; car samples average \$19.50.

Sao. BALCHRA.—The north drift on the 1150 level, from the top of the 1200-level raise, has been extended to a total distance of 62 feet and stopped. From the end of it a west crosscut has been started and is out 11 feet. The face is in a mixture of clay, porphyry and low-grade quartz.

We continue to save about seven tons of fair-grade ore per week from the south raise on the 1150 level.

CAWON POINT.—The south drift from the top of the 700-level raise on the 600 level is now out 63 feet. The face is in a mixture of clay and porphyry. The south drift on the 7th floor of the 700 level raise is now out 54 feet. The face is in porphyry and low-grade quartz. The south drift from the station on the 500 level is out 37 feet. The formation in the face is in a mixture of porphyry and low-grade quartz.

SIERRA NAVAJO.—The south lateral drift from the intermediate tunnel has been advanced 30 feet; total length, 633 feet; face in hard porphyry.

Have started a joint west crosscut near the north line of the Union mine from the north drift 1520 feet west of the shaft, 900 level, and advanced same 15 feet; face in hard porphyry.

CHOLLAR.—The north drift, 100 level, has been extended during the week 22 feet; total length, 139 feet; face in quartz and porphyry.

The west crosscut on this level, 300 feet south of the north line, was extended 32 feet; total length, 132 feet; face in a mixture of soft porphyry and quartz.

ALTA.—On the 725 level the south raise continues to look well as we advance upward, and the intermediate winze shows a decided improvement, gold predominating in the assays over the silver. Average assays, \$38.60, \$26 of which is gold. There is no change in the drift from the north raise.

POROSI.—The south drift on the 450 level has been advanced 24 feet; total length, 348 feet; face shows streaks and bunches of fair-grade quartz. The south drift, 50 feet above the 450 level, is out 82 feet, having been advanced 27 feet; face in porphyry, clay and quartz.

BELCHER.—On the 850 level the north drift has been cleaned out and retimbered a distance of 30 feet, making its total length 355 feet from the shaft. During the week 27 tons of fair-grade ore were extracted and hoisted to the surface.

UNION SHAFT.—Have started a joint west crosscut near the north line of the Union mine from the north drift, 1520 feet west of the shaft on the 900 level, and advanced same 15 feet; face in hard porphyry.

WARD COMBINATION SHAFT.—The west drift from the station, 820 level Ward shaft, is out 750 feet from the shaft; face in porphyry and seams of quartz.

BULLION.—The west drift from the station, 820 level, Ward shaft, is out 750 feet from the shaft; face in porphyry and seams of clay.

BONANZA TALK.—*Virginia Enterprise*, April 24: The ore discovery in the vicinity of the 1650 level of the Consolidated California & Virginia caused a sharp upward movement in that stock in yesterday's opening session of the boards, and the stock closed strong last evening at an advance of 30 cents above last week's top quotation.

The recent ore discovery is not in the vicinity of the old workings, but is in entirely new ground, and further important developments are among the probabilities.

Public feeling is ripe for a market, and should the present discovery widen out either

above or below, an advance in price of the stock equal to that following the discovery in 1886, is predicted by sanguine operators, while the more conservative are talking the price up to \$30 per share.

Superintendent Sharon of the Yellow Jacket, Belcher and other Gold Hill mines returned to the Comstock yesterday from a business trip to San Francisco. He says there are over 200 tons of fair-grade ore accumulated in the bins at the Yellow Jacket, and about the same amount at the Belcher, and that the billion returns from this ore, when crushed, will more than cover operating expenses the current month.

Herman Zadig, the well-known mining operator, arrived on the Comstock on Sunday to inspect the properties under his control. Mr. Zadig is confident that the Comstock share market will show an important advance in prices before the close of the current month.

The following official mining letters were filed at the local offices on Saturday:

OCCIDENTAL.—From the 1100 level above the 400 level we continue to extract about eight tons of ore per week showing an average value of \$46 per ton.

KENTUCK.—On the 1100 level the south drift from the top of raise No. 1 is in 59 feet, and continues in fair-grade ore. On the 1200 level the south drift from the Yellow Jacket incline is at a total distance of 51 feet, the face in low-grade ore.

JUSTICE.—The south drift from the winze sunk from the Blaine tunnel has been extended 15 feet since last report; total length 76 feet. The face shows a width of about three feet of ore which is saved for pay.

CONSIDERED FAVORABLE.—*Enterprise.* Connections having been made with the old Mexican shaft, the work of extending the central tunnel westward will begin this week. The ground to be penetrated is favorable for an important development, as the crosscut is being advanced in a region interlaced with small veins of low-grade quartz, which indicate the proximity of an ore body as surely as the roots of a tree are evidence that the trunk is not far distant.

Flowery District.

CHANGING THEIR SYSTEM.—*Virginia Enterprise.* Several owners of blanket sluices along the course of Six-Mile Canyon creek will turn their attention to placer mining, as the return from sulphuret concentrations obtained from ore tailings barely pay expense. Coarse gold has frequently been found in the bed of Six-Mile Canyon creek, but not in sufficient quantities to make it remunerative. The surface workings of locations in Flowery district all show a preponderance of gold in the quartz veins; and, as the low price of silver has made mining for that metal unprofitable, prospectors are devoting their time exclusively to a search for the yellow metal, and Flowery district offers better inducements to gold-seekers than any other locality in this county.

Ferguson District.

A mining expert, who recently returned to Salt Lake from a visit to Ferguson district, says that it is the greatest camp he ever saw. He says that it is safe to estimate that there are 1,000,000 tons of ore in sight in the district that will assay from \$10 to \$100 in gold. The camp is now conveniently located, and it will cost at least \$50,000 to get water in to work the ores cheaply. The ores that are being worked at present have to be hauled 35 miles, either to Hiko or the Condor mill at Pioche.

ALASKA.

ALASKA PRICES.—The *Juneau News*, on authority of Hank Wright, a miner, says that Miller creek last year produced \$100,000 from 46 claims. Wright and his partners took out \$14,000 last season. There were six to eight feet of loam and ice above the pay gravel to be removed. The discovery claim yielded \$6000 last year. Four other partners took out \$6000 each. The French brothers got \$8000 in dust. Wright believes that richer diggings can be found farther up the stream. At Franklin gulch 35 men last year averaged \$1000 to \$1200 each. There are about 300 people in the Yukon country and about 150 wintered at Forty Mile, which contains 80 cabins. The current prices there are: Flour, per cwt., \$6 to \$8; bacon, 25 to 40 cents per lb.; sugar, 15 to 20 cents per lb.; beans, 12 cents per lb.; Caribou meat, 7 to 10 cents; clothes, \$20 upwards; gum boots, \$10 to \$12, and board \$40 per month.

COLORADO.

REPORT ON DUNCAN ORE.—Duncan is feeling the effects of the mining upheaval. Everything, says the *Garrison Tribune*, is on the move, everybody is busy and in high spirits, and the mines are showing better than ever. Several new business houses have recently been erected, and many new residences have sprung up in the town. All the mills now there are running, and several others are soon to be built. Some Salt Lake investors who recently visited the camp selected samples from the Puritan mine and give this as the result of their tests: In the first-class concentrates they find 3.4 ounces of silver and 39.4 ounces gold, representing a value of \$780 per ton. Considering that 30 per cent of the value in this ore is in free gold, and had been taken out before the test was made, it shows that the mines are immensely rich. Second-hand concentrates show a value of \$48 and the tailings \$4.60. This also demonstrates that the deeper workings show a much higher value than the surface. The ore in the pay streak is a quartz carrying copper and iron, and has widened from a mere streak at the surface to about eight inches at a depth of 150 feet in three different levels. Besides this, there is a body of from four to eight feet of low-grade ore which is now being milled in which there is great value. There is also some

tellurium in the vein. Messrs. Ernest and Kelly, two experts from Denver, who were sent in to investigate gold properties in this camp, will report favorably, the *Tribune* says. They say the formation is the same as a camp of their acquaintance in New Mexico, where ore from a two-foot vein was freighted by wagons a distance of 105 miles and made a great success, and the veins here are much larger and give promise of being much richer.

AT YANKEE HILL.—Work on the big Alice concentrating mill was started on Wednesday. The concentrator will be what is known as the Stoddard concentrator, a German invention, and similar to the one used by the Smuggler mine at Aspen. It will have a daily capacity of 100 tons. McFarlane & Co. of Central City have the contract for building the mill, which, when finished, will have cost \$60,000.

SPOOK CITY.—Ford Creek district, near Saguache, is attracting the attention of mining men and is rapidly filling up with prospectors. The principal settlement is Spook City, and its enterprising residents have sent on a petition to Washington for a postoffice. Biedell camp, in the same vicinity, is also looming up, according to the *Saguache Crescent*.

IDAHO.

A BIO ENTERPRISE.—*Lamar Nugget.* Parties, backed by abundant capital, are now endeavoring to make negotiations for the greatest mining enterprise ever proposed in Owyhee county, if not in Idaho. Notwithstanding the many millions in bullion which War Eagle mountain has produced, all who are familiar with that pile of granite, ribbed and seamed with mineral-bearing veins, must admit that the wealth taken from them is comparatively nothing in proportion to what still remains. The proposed tunnel, running directly across the course of the veins, would cut them at depths of from 1400 to 2000 feet. The first series of veins would be reached by the tunnel at a depth of 1400 feet, at a distance of less than 4000 feet from its mouth. Extending it 4000 feet farther, almost every vein in the mountain would be cut. The mouth of the proposed tunnel would be where to day grass is growing and summer is on, while still the surface of the mountain overtopping it is so buried in snow that it is almost impossible to reach it with teams. The water power is there in sufficient supply to work all the machinery required to drive the tunnel and to run all the mills required to reduce the ores.

SOLD TO A SYNDICATE.—*Anaconda Standard.* From Idaho comes the news that Governor Wilson has sold his immense placer mining machinery and claims to a wealthy English syndicate. The sum which Mr. Wilson receives is in excess of \$250,000. It is a handsome reward for the thirty years of toil which Governor Wilson has devoted to the development of the great property. Anywhere in these regions well-informed mining men will tell you that in point of natural richness and systematic development Ben Wilson's great properties at Pioneer lead the best of them. In the last quarter of a century it is estimated that not less than \$100,000,000 in gold has been taken from the wonderful placers of the Basin. Wilson's vast property has been worked constantly during all of that time, and for years a day and night shift kept the sluice boxes full.

TO WORK UNDER WATER.—The *Shoshone Journal* says: Root Brothers and Dnnbar, of Chicago, are making extensive preparations to mine the bare in the bed of Snake river, between the Shoshone falls and the Blue lake. The bare are from six to eight feet under water and the dirt will be raised with centrifugal pumps. The machinery, consisting of boiler, engine and pumps arrived here Wednesday from Chicago. A flatboat fifty feet long will be anchored in the middle of the stream, over the bar, and on this the machinery will be placed, and the dirt and gravel will be raised from the upper end of the boat, and run over the gold-saving machine, then the waste will be dumped into the river at the lower end of the boat. While this is a new system of mining bars there is no doubt but that it will prove successful, and as soon as it is demonstrated a success, thousands of Snake river bars, now under water, will be worked.

MURRAY CORRESPONDENCE.—With the opening of the mining season Murray is in better spirits than for some years past. There is promise of an abundance of water for placer operations. The "old wash," which lies on the slope facing the south and therefore gets the water from early melting of snow, is now the scene of greatest activity. There are booming operations in a number of the side gulches. On Tiger gulch Messrs. Williamson and partners will soon resume. Booming began on that gulch last fall. The Golden Chest is employing about 30 men and getting a good grade of quartz. The 10-stamp mill is kept constantly at work and crushes about 30 tons every 24 hours.

The Mother Lode mill is also running ten stamps steadily with water power and turning out gold bricks as usual. They contemplate adding a rope tramway to the plant soon, which will let their ore cars right down into the mill.

The Messrs. Coplen have begun the erection of a quartz mill on the "Daddy" lode, and will mill quartz obtained from the same vein as the Mother lode. They expect to have a capacity of ten stamps eventually, but are only putting in five stamps now.

There are many miners here seeking employment, and it is not likely the miners' unions will order any strikes again soon in this country. Their interest is now to assure timid capital and thus get employment. The roads will soon be open for traffic, a large number of men being now at work shoveling through the two-mile divide, opening a wagon road to the railroad at Osburn.

MONTANA.

THE CURLEW MINE.—*Missoula Silverite.* The Helena and Victor Mining Company is working a large force of men on the Curlew mine and is running the concentrator. The ore chute recently discovered on the 500-foot level is improving in size and grade, and it is thought it will equal those ore bodies which have produced so much ore from the upper levels. This chute is thought, however, to be entirely distinct from any other heretofore found in the mine. It is 400 or 500 feet away from the main contact and does not seem to be connected with the other ore bodies.

OREGON.

IN JOSEPHINE COUNTY.—*Grant's Pass Courier.* Fred Maher has struck a bonanza between Thompson creek and Williams creek. He has found a two-foot vein of gold-bearing quartz which mortars from \$2 to \$20 to the pan. This is no pocket, but a true fissure vein, and bears every evidence of being a permanent thing. A strike of this kind would be heralded in some countries with a column article and four scare-head double-pica capital lines, but they have become too common in Josephine county to get excited over.

The success of the tunneling in the Ashland mine settles the question as to permanency of mines in southern Oregon. Heretofore the cry has been that our veins of gold "peter out" or become base at the depth of a few hundred feet, but this tunnel at Ashland is 600 feet long, and has found a richer and wider vein of quartz than that upon which the mill had been crushing for nearly a year with such good results.

Josephine county's gold dust has helped tide over the hard times. During the past two years an immense amount of prospecting has been done and a silent stream of yellow dust has been flowing out in consequence. Nobody, unless directly interested, ever sees this product going on its way to market, but the coin derived therefrom is all spent here, and thus Grant's Pass business men have had fewer sight drafts to pay than those of any town in southern Oregon.

JACKSON COUNTY.—*Times.* Conger & Arnold have two Tremain quartz-mills on the Governor Chadwick mine on Rogne river, opposite Fort Lane, and will commence crushing ore this week. They have bonded a large area of land. It is rumored that Mangum & Stewart of Tacoma, who purchased the Grandpner place, have bonded the Sterling Mining Co.'s property at a high figure. Capt. C. H. Thompson, of Detroit, Mich., who has been in the valley for a few weeks looking at various mining properties, has arranged to bond the Braden ledge in Gold Hill district. He has been interested in Colorado mining property with Gen. Russell A. Alger, and it is supposed that the latter gentleman is also in the present deal.

Medford Mail: W. H. Rhoten and A. W. Sturges are placer mining up on Jackson creek, and are meeting with success in big chunks. Last week they took out 68 ounces of clear gold from their flume, as the result of a two months' run. They have not made their cleanup yet, nor will they do so as long as the water supply holds out, but when they do rich returns are expected.

BAKER COUNTY.—*Democrat.* The establishment of a smelter and sampling works in Baker City is in the interest of the mine-owners directly. The man who is the possessor of a mine and too poor to erect a mill thereon, or unable to purchase development work, will find a smelter a godsend. The Baker City Sampling Works started up yesterday with a reduction capacity of ten tons of ore per day. The run started on ore from the Gorman & Reynolds mine, in Virtue district, and good returns are expected. Other consignments of ore are contracted for, and it is thought the mill will be kept in steady operation.

UTAH.

SOME BIG FINDINGS.—Writing from Clifton regarding the Troy ledge, a *S. L. Tribune* correspondent says: "Two assays were made from this rock on the 27th day of January last by Charles Carter, the superintendent of the Gold Hill mills, the first of which gave \$5860.40 in gold and 208.03 ounces in silver. The results of this assay, as I am informed, seemed to the assayer as being so extraordinary that he supposed a mistake had been made, and, to satisfy himself that he was not mistaken, he tried a portion of the remaining pulp in washing with a horn. This at once convinced him that the ore was extraordinarily rich, and then to test the first a second assay was made with greater precaution than before, resulting in an exhibit of \$5892.20 in gold and 214.7 in silver. To add to the richness of the above, it should be stated that the writer hereof prepared the pulp for assay himself, and that in so doing it was his aim to put about one-tenth of the silver pulp to nine-tenths of the gold pulp in the amount sent to the assayer, so that to multiply the silver part of the assay by ten, you have a result of a fraction over 2354 ounces of silver. At this writing no work below the surface has been done, but old miners who have examined the ledge above the surface state that at least \$25,000 can be seen in sight. To the old miners and prospectors who have been familiar with the district for the past 15 or 20 years, the above statement would naturally seem overdrawn; but from those who are now upon the ground, your correspondent has no fear of being contradicted."

WYOMING.

WYOMING MINES.—*Cor. Denver Record.* The outlook in this section is favorable to an advance in mining work at an early date. More real hard and effective work was done in the Douglas and La Plata mining districts the past winter than all the years since valuable mineral was found in the Medicine Bow range. The great snowfall in the mountains west of this city insures ample water for a lengthy run in

the placer mines of Douglas creek and its numerous tributaries. The Douglas Consolidated Placer Mining and Milling Company is making preparations to put quite a force of men to work on its property at as early a day as practicable. This company's property consists of over 2300 acres of placers, located under the mining laws of the United States, and so taken as to cover the best of the first bottom land of the creeks, in the Medicine Bow range of mountains, townships 13 and 14, north range 78 and 79, west of the sixth principal meridian, in Albany county, State of Wyoming, and at an altitude of from 8500 to 9000 feet above sea level. The soil is composed of gravel wash of granite, gneiss, quartz and syenite and detritus of the surrounding hills, with a bedrock of granite and gneiss. The depth of the soil or wash is from 4 to 20 feet, the quality a heavy gravel with black sand, and occasionally a few boulders, but none so large but what can be readily handled. The bars are of varying extent and width, from a few to 200 acres. Pine, spruce and fir balsam cover the hills, abundant and of good quality for saw timber and all mining purposes. The timber is tall and straight, and there are many good sawmill settings, rendering the purchasing and transportation of lumber unnecessary; along the creeks are open parks covered with rich grass and willows. These claims are well watered by numerous creeks running through, the snowfall in winter being heavy, and the rainfall abundant during the summer months. Douglas creek, the principal stream, runs through most of the claims.

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market Street.

FOR THE WEEK ENDING APRIL 17, 1894.

- 5,843.88.—CALCULATOR.—D. L. Albert, S. F.
- 5,843.89.—SALT AND PEPPER BOX.—C. M. Berry, S. F.
- 5,843.90.—CARINET.—A. Beyer, Spokane, Wash.
- 5,843.91.—LAWN SPRINKLER.—S. M. Black, Pasadena, Cal.
- 5,843.92.—DYNAMO.—H. E. Dikeman, Berkeley, Cal.
- 5,843.93.—CAR COUPLING.—Wm. Dunlap, San Diego, Cal.
- 5,843.94.—FRUIT KNIFE.—N. B. Hale, San Bernardino, Cal.
- 5,843.95.—ELECTRIC METAL PIPE.—C. S. Hamilton, Los Angeles, Cal.
- 5,843.96.—HOCK.—D. W. Holden, Gardiner, Ogo.
- 5,843.97.—SASH FASTENER.—Grate M. Kimball, Oakland, Cal.
- 5,843.98.—METAL CAN.—John Lee, San Mateo, Cal.

- 5,844.15.—DISH CLEANER.—F. H. West, Portland, Ogo.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

SASH HOLDER.—William H. Masterman, Oakland, Cal. No. 518,413. Dated April 17, 1894. The object of this invention is to provide an improved holder which is adapted to tighten and fasten window sashes in their frames, and it is especially useful for car windows, or others which are subjected to considerable jar and rattle. It consists of a spring-actuated plate having one edge beveled; a separate strip let into the sash groove having a beveled face for the beveled edge of the plate; a shank at the center of the plate, adapted to enter a recess in the sash, with coil springs seated in recesses in the sash to bear on opposite ends of the sash; and a face-plate, covering the sash with an elongated slot through which a pin or stud from the shank projects; and a vertically-disposed lever pivoted at one end to the face-plate, with a finger piece upon the opposite end by which the device is operated.

CALCULATOR FOR WAGES, ETC.—David L. Albert, San Francisco, Cal. No. 518,438. Dated April 17, 1894. The object of this invention is to provide an implement which is adapted to mechanically ascertain the wages of men for any number of days and parts of days at any rate per month. It consists of disks pivoted concentrically and mounted one above the other with a suitable handle and back plate upon which they turn. These disks are marked one with the number of working days in the month and spaces for parts of days, a disk behind this of sufficiently larger diameter to expose figures around the periphery indicating days and quarter days, still another disk behind this of larger diameter indicating half-day divisions, and a third disk indicating three-quarter divisions. Above all these is fixed a disk with a radial slot upon one side of which are marked the rate of wages per month between any given figures, as from \$30 to \$75, depending upon the class of labor that is being paid for. Each of the first named disks have concentric circles with the wages payable for the number of days and parts of days, and adapted to coincide with the radial lines of figures just described, so that when any of these disks are turned to bring certain figures in conjunction with those upon the outer disk, the amount for the given number of days will be instantly determined.

Market Reports.

The Markets.

SAN FRANCISCO, April 26, 1894.
Silver advanced steadily through the week, going above 64c. On the last day of '93 it was 68c for 1,000 fine in New York. It has been down to 61½c, but the probabilities do not favor a further drop.

The local bullion, money and exchange quotations current are as follows:

Commercial Loans, % per annum	7@8
Commercial Loans, prime	6@9
Call Loans, gilt-edged	7@8
Call Loans, mixed securities	7@8
Mortgages, prime, taxes paid by tender	7@8
New York Sight Draft	12½c
New York Telegraphic Transfer	17½c
London Bankers', 60 days	\$4.88½
London Merchants'	\$4.85
London Sight Bankers'	\$4.89½
Refined Silver, per ounce	64½
Mexican Dollars, nominal	53@53½

Latest London cables say there was distinct improvement to-day. English railroads were bought on favorable traffic returns, but speculative stocks were also bought, including Americans, which show fractional gains, closing steady. Silver was up to 23½d on the Indian buying, said to be speculative on the belief that the mints will reopen. This rumor depressed Rupee paper. The Indian Council sold 59 lakhs of Rupees at rates ranging up to 13 19-32. The amount offered for next week has been increased to 60 lakhs. Seventy-one thousand pounds of gold were bought.

New York Prices.

NEW YORK, April 26.—Following are the closing prices for the week:

	London.	N. Y.	Copper.	Lead.	Tin.
Thursday	28½	63	9 50	3 20	19 60
Friday	28½	63	9 50	3 20	19 60
Saturday	28½	63	9 50	3 20	19 60
Monday	29	63½	9 50	3 20	19 60
Tuesday	29½	64	9 50	3 25	19 70
Wednesday	29½	64½	9 50	3 25	19 70

Mining Share Market.

SAN FRANCISCO, April 26, 1894.
The "idle millions" of dollars about which so much has been said and sung, appear to be afforded an outlet in the stock market, for, according to the real estate and mercantile reports for the week, there was more money in Pine street operations than any other line. Every stock on the list has shown the effect of the reawakened interest and not for months have there been so many buyers. When people cannot get six per cent for their money, and are chary about putting it into ordinary business enterprises, they naturally turn to some outlet for speculative transactions. The increase in the price of silver bullion also lends an increased argentiferous lining to the clouds that so heavily lowered.

The break in the market Tuesday was followed by an advance. Con. Virginia selling up to \$5, the strike on the 1650 level being to many a warrant for investment. There was a flurry Wednesday, occasioned by exaggerated reports of fire in Virginia City, which in reality amounted to nothing, but the day closed with sales of Con. Cal. & Virginia aggregating 10,000 shares. Enthusiastic operators say it will go to \$30. In this regard the old advice is good: "Don't never predict unless you know." It is evident, however, that the general feeling favors a lively market. One year ago Con. Cal. & Virginia sold at less than one-half its present price.

A VERY successful trial has been made in Sweden to fell trees by means of electricity. The process is very simple, and consists in passing a platina wire round the stem of the tree and heating it to a glow, cutting through the same much in the same way as one would divide a piece of soap with twine. One of the chief advantages is that the cut end of the log being burnt gives the log a better quality.

J. F. CROSETT, Commission Mining Agency,
628 Sacramento St., San Francisco, Cal.
Buy and Sell Meritorious Mining Properties. I have orders for Income-Paying Mines at the present time. Have also some good properties for sale. I want more mines to offer to purchasers and also desire more purchasers to examine properties I have to offer. Correspondence solicited.

Coast Industrial Notes.

—The sale of the Union Mill has been concluded. The price paid by Sperry & Co. was \$290,000.

—The Fulton Engineering and Ship-Building Works is completing the new ferry-boat Sausalito, and expect to have it ready for launching in about a month.

—The Keystone Supply Company has incorporated with a capital of \$100,000, fully subscribed. Directors: M. J. McDonald, J. S. Emery, Robert McF. Doble, J. H. Isham, Charles E. Anderson.

—The board of directors of the Pacific Improvement Company has decided to place property valued at from \$10,000,000 to \$12,000,000 in the charge of the land department of the Central Pacific road for disposal.

—The Baldwin Livery Company has filed articles of Incorporation. Directors: J. G. Spaulding, C. W. Nevin, H. W. Potter, J. H. Banfield, W. H. Ward. Capital, \$10,000, of which \$4000 has been subscribed.

—The Hutchison Water Gas Furnace Company has incorporated with a capital of \$100,000, fully subscribed by the following directors: E. O. Burns, Vincent Wallace, Owen Burns, Samuel Brown, X. E. Burns.

—The Prosper Fishing and Trading Company is incorporated. Directors—William Hunter, William Schrader, Elias O. Dahl, Edward Kruse and Emil T. Kruse. Capital stock, \$160,000, of which \$1350 has been subscribed.

—The Vancouver, Klickitat and Yakima Railroad has been sold to New York capitalists for \$110,000. It is understood that the road will be extended to connect with the Northern Pacific. The name will be changed to the Portland, Vancouver and Northern Railroad.

—The annual meeting of the stockholders in the Union Pacific Railway Company was held last Wednesday. The report of the directors shows a deficit for the year on the whole system of \$2,595,841, compared with a surplus the previous year of \$2,006,757. The heavy decrease was due to the silver crisis, the failure of the Kansas wheat crop and the general prostration of business. The control of the stock is going abroad. The Oregon Short Line and the Utah Northern show a deficit of \$238,356 as compared with a surplus in 1892 of \$744,660. The deficit for the Oregon Railway and Navigation system was \$199,459 in 1893, compared with \$1,564,441 in 1892.

—There are twenty-one firms in the lumber combine, and of the mills in the combine but nine are idle. There is a little advance in the price of clear and surfaced lumber, which is quoted at \$22 per M.; rough lumber, \$14. President Gray of the association says: "The consumption of redwood lumber in 1893 amounted to 240,000,000 feet. This includes all the material which left the mills. This being a dry year, we figure on a somewhat smaller demand. We have agreed to cut for the year 200,000,000 feet, and if there is any more needed we will supply it. You understand there is no desire to limit the supply and hull the market. We merely do this to prevent the market from being overstocked. Lumber has been selling at ruinous rates, and it would continue to do so if some restriction were not put on the output. The Navarro mill put out last year about 20,000,000 feet of lumber, the result being that it is now in the hands of the Sheriff. They had 500 men living there, many of whom had their families. All of the men had to go, and many of them are journeying eastward in the ranks of the unemployed. We wish to avoid any such end as this."

—The Bradstreet Mercantile Agency reports 11 failures in the Pacific Coast States and Territories for the week ending Friday, as compared with 16 for the previous week and 21 for the corresponding week of 1893. There were 91 failures in the Pacific Coast States and Territories for the month of March, with assets of \$270,366 and liabilities of \$453,947, as compared with 106 for the previous month, with assets of \$399,080 and liabilities of \$640,658, and 71 for the corresponding month of 1893, with assets of \$416,143 and liabilities of \$542,535. The failures of the past month are divided among the States and Territories as follows:

	No.	Assets.	Liabilities.
California	74	\$236,966	\$384,447
Oregon	8	12,600	25,800
Washington	9	20,800	43,700
Totals	91	\$270,366	\$453,947

The following are the causes assigned for the failures: Incompetency, 26; inexperience, 8; inadequate capital for the business undertaken, 46; injudicious crediting, 3; neglect of business and bad habits, 2; excessive competition, 1; unfavorable circumstances, floods, fires, etc., 4; fraud, 1.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for packing on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.
IMPROVED SINKING PUMP.—Buckets and clack changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clack cannot be changed under water. The self-lightening and self-lubricating stuffing box and new bucket also saves expense of dropping extra pumps.
WM. NANCE, Grass Valley, Nevada County, California.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 60-horsepower engine and 46-horsepower boiler, with ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building, a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1014 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

MACHINE WORKS,

Steam Pumps Steam Engines

And All Kinds of MACHINERY.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from Geo. A. Debris in the Nevada mine, near Gilsonville, Sierra county, to deposit tailings behind log and brush dams in a ravine; from John Egbert in the Nooday mine, near Sierra O. Y. Sierra county, to deposit tailings on flat ground; from Douglas Perkins in the Cleveland mine, near Sierra, Sierra county, to deposit tailings behind a log dam in Rock creek; from John Eyrand and Jean Lazzer in the Indian Hill mine, Plumas county, to deposit tailings in a depression behind a rock dam; from Dubra, Wilder & Co., in their mine in the Nip and Truck mines, near Barger, Butte county, to deposit tailings behind a dam in Robinson ravine; gives notice that a meeting will be held at Room 92, Flood Building, San Francisco, Cal., May 1, 1894, at 1:30 P. M.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It is a volume of useful tables for ready reference, in which the results of accurate calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are both met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:
General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.
Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of sluices, flumes, dams, pipes, and water on heavy Grades. Methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdies, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

UNION IRON WORKS.

CORNER FIRST AND MISSION STS., SAN FRANCISCO, CAL.

MANUFACTURERS OF

MINING AND MILLING MACHINERY.

Automatic Cut-Off Engines, High-Speed Engines, Hoisting Engines, Quartz Mills,
 Manty Chili Mills, Rolls and Concentrating Machinery, Dodd Sigmoidal Water Wheel
 PUMPS (Cornish and Other), Copper and Lead Furnaces, All Classes of Marine Work,
 SHIP BUILDERS, BUILDERS OF U. S. WAR SHIPS. HYDRAULIC LIFT DOCK.
 NEW YORK OFFICE, 145 BROADWAY. Cable Address, "UNION."

MINING AND SCIENTIFIC PRESS.

AND PACIFIC ELECTRICAL REVIEW.

An Illustrated Journal of Mining, Mechanics and Popular Science.

VOLUME LXVIII. Number 18. SAN FRANCISCO, SATURDAY, MAY 5, 1894. Three Dollars per Annum. SINGLE COPIES, 10 CENTS.

A Southern California Enterprise.

In common with other parts of the State the progressive element in southern California recognizes the need of utilizing electrical force in developing natural resources, the idea being to secure the maximum of power at the minimum of cost.

The highest mountain range in the southern part of the State is just northeast of Redlands, and down the steep slopes flows abundant water, giving great chance for developing electrical power. The Redlands Electric Light

Drift Mines at Deadwood.

Every mining State and almost every mining county has its Deadwood mining district. More often than otherwise it is a good mining district. Placer county is no exception in either respect. Deadwood is a small drift-mining locality, situated on the divide between two of the tributaries to the middle fork of the American river, seven miles northeast of Mich'gan Bluffs. Through the summit of the divide cross diagonally the buried channels of some of the ancient rivers so extensively and profitably mined

The Silver Question in Japan.

Japan is as interested in the world-wide silver question as England or the United States. That country is on a silver basis, and the rise in the purchasing power of gold is as manifest in the island empire as elsewhere. Recent letters from there say that a dollar sent there buys two dollars' worth. Frank Carpenter writes: "I made out a draft of \$100 on my New York letter of credit at the bank this morning and got \$208 for it, and the money I have brought with me has doubled in value. This makes trav-

1-Headgate Looking West.
2-Headgate Looking East.

HEADGATES OF REDLANDS ELECTRIC POWER COMPANY.

3-Sand Box.
4-Power House.

& Power Co. organized with a capital stock of \$200,000, and started work in Mill Creek canyon. A tunnel 168 feet in length and 7250 feet of steel pipe brought the water to the power house, where the requisite machinery enables the company to utilize 3000-horse power. Our illustration gives a general idea of the headgates, etc.

Such enterprises are what go to make a State. The man who made two blades of grass grow where but one grew before used to get the applause which is now bestowed on the man who makes work for five men where before there wasn't work for one.

The company supplies Redlands and Mentone with light, the Union Ice Co. with power, and is prepared to furnish cheap light and power to manufacturing enterprises locating in that vicinity. Mr. F. G. Ferand is the efficient secretary of the company, to whom inquiries may be addressed.

THE "gold reserve" has again dropped below the hundred-million mark. It is now a question, Will Secretary Carlisle issue another bond call for a \$50,000,000 loan? There is little to the gold reserve beyond ancient and dusty tradition, but it serves a purpose which has been worked for all it is worth.

for gold in Placer and other counties. Prominent among these is what has been known as the Devil's Basin channel, which, 25 years ago, was mined down stream as far as drainage could be had, and yielded a very large amount of gold. The outlet and continuation of this channel on the west side of the ridge has been prospected for during many years and is now believed to have been found. The owners of the Clifton mine, Messrs. Dixon and McCarty, are the fortunate individuals. The channel mined so profitably in the Center mine has turned and enters the Clifton, through which it can be traced by the rims, and he identified as the old Devil's Basin channel. Where it enters the Clifton, the channel is about 60 feet wide; it is in soft bed-rock, with four to eight feet of gravel under a cement roof. In the Clifton the conditions for mining will be very favorable, and a tunnel now being pushed will soon reach pay. Once again mining in this channel, Deadwood will regain some of its old-time importance as a gold-producing camp.

TEN MILLION DOLLARS' WORTH of gold bullion was shipped last week from the New York Assay Office to the Philadelphia Mint to be converted into coin, which makes \$50,000,000 recently received in that city from New York.

eling comparatively cheap, and although I have been paying four dollars a day at the Grand hotel in Yokohama it really costs me only two."

A foreigner, resident in Japan, with a \$3000 annual income, really gets \$6000, so far as the purchasing power of each dollar is concerned.

Of course this cannot continue, for the equalizing forces of natural law will sooner or later work the same way there as farther east and west, but for the present the income-receiving class are "in clover."

MINING capitalists and metallurgical experts have held a meeting in Denver to talk over the merits of different methods for treating Cripple Creek, Col., low-grade ores. The question resolved itself into a choice between the cyanide process or the chlorination process. It is reported that the leaning of the majority is toward the latter. The statement was made that the ore could be treated at a cost of \$4.50 per ton, and with a saving of over ninety per cent.

THE question is asked: "Why is England so determined in its exclusive gold policy?" The answer is simply this: England produces no silver.

The Limitations of the Gold Stamp Mill; A Phantom of the Mines—"Seeing the Oge," 278. The Cornish Tin Streams; Mt. Shasta, 279. Diamond Mining; Literary Note, 288. Coast Industrial Notes, 286. Recent Patents, 287.

WHETHER for good or ill it is evident that party politics will figure in the fight for the remonetization of silver. Thos. Carter has an article in a current magazine wherein he says that the next Republican platform will have a plank demanding the restoration of bimetalism. As Mr. Carter is chairman of the National Republican Committee he evidently speaks authoritatively.

SAYS the *Coal Trade Journal*: "Circulation is not always a good criterion of the advertising value of a paper. A medium may bring bushels of replies but no sales. A 'fake' paper of enormous circulation may do for a penny advertiser, but it will not pay one who must have more than five dollars to make a sale. A well-recognized trade paper 'right in line' may bring but one reply, but that one may make a sale involving thousands of dollars."

J. W. GRACE & Co.'s crude oil experiment appears to be so far a success. They recently fitted up a steamer—the Bawnmore—with tanks and sent her to Payta, Peru, where the crude oil from forty-nine wells, six miles in from shore, was piped into the vessel, carrying 840,000 gallons. The trip was satisfactory, and Grace & Co. have the credit of inaugurating a new industry. The city gas companies will take all the crude oil brought here. Oil from the Payta district is almost universally used for fuel in every part of Peru.

THE Cooxey movement which thundered in the index proved a fiasco. Cooxey got to Washington, D. C., last Tuesday with 500 of the 500,000 that he was going to lead. He and his lieutenant, Carl Browne, tried to address the crowd on the steps of the National Capitol, but he was compelled to leave the grounds, while Browne was taken to jail. So those who expected that the next gale that sweeps from the East would bring to our ears the clash of resounding arms must wait a while for the sounds of conflict. The whole thing illustrates general popular discontent; but the probability of serious present trouble is greatly lessened by the result of last Tuesday's demonstration.

THE industrial features of the week have been the collapse of the Cooxey movement, the settlement of the strike on the Great Northern Railroad, and the widespread continuance of the strike of the coal miners, with considerable attendant violence. Over 130,000 coal miners have struck—about 50,000 in Pennsylvania, the rest in Ohio, Illinois, Alabama, Tennessee, Kentucky, West Virginia, Indiana and Iowa. The strike is a protest against last year's reduction in wages. It will last, probably through the month, with the usual result. The strike is only in the bituminous coal districts, and the anthracite coal trade contemplates the situation with great cheerfulness.

Different Only in Terms.

The commanding value of gold is strikingly illustrated in all revolutions, or crises, when it always appreciates in value; that is, in purchasing power. Thirty years ago, when there was a grave conflict, it increased in value, that value being then expressed by its being sold at a premium, a dollar gold being worth \$2.35 in the currency then circulating.

There is as great a conflict now going on; there are no uniformed armies, no generals on horseback, nor pomp and circumstance of battle array, but the fight is on and is as distinctly manifest as the war of '61-'65. That was "a civil war;" this is a national one. As then, so now; gold has increased in value; so far as gold is concerned the situation differs only in terms. Gold is not quoted at a premium as thirty years ago; the tilt is the other way, and that which gold buys is reduced in price. The effect, however, is precisely the same. The present rise in gold is registered in the fall in the prices of real estate and staple articles.

The Republic Only an Opportunity.

It would seem that a good deal that is written in newspaper offices about "the Industrial Army," and set in type, and read by the wise and otherwise, is based on a wrong conception of the facts. A large proportion of editorial statement concerning the Cooxeyites shows considerable confusion regarding equality. People often get mixed up on "equality." There is political equality for everybody; that is the broad basis upon which we do business as a government; but that does not involve nor include personal or social equality. This republic of ours is not an invention for raising or reducing all men to a level. It is not a commune nor a brotherhood; it is an opportunity to let all men find their own level. They do it, and that's the chance this government gives. That is its merit, its value; as long as it does that it has reason for existence; when it ceases to do that it has not. It is doing that now, in spite of all its foes and many of its friends who are well meaning enough, but who argue on current troubles from a mistaken standpoint. Sincerity in these matters is not enough; a little understanding of the facts is requisite.

British Hopes.

The London *Mining World* of April 14th gives an account of the Lead Hills Silver-Lead Mining Company's annual meeting; a verbatim report of the proceedings. It transpired that the only thing that prevented the company from making a profit during the year was the low price of lead. When asked what the outlook was for higher prices the chairman said that there was some hope; that the Congress of the United States was about to pass a tariff bill that would take off about fifty per cent of the present duty on lead, and that would be a great help. He hoped that bill would be passed in the autumn. This statement was received with "cheers."

Then the secretary made a speech. He said "the last quotation of lead be had seen in the New York papers was \$3.40, which was equivalent to £15 17s 4d in English money. If a reduction were made in the import duty of one cent it would mean a reduction of £4 13s per ton. This sum, deducted from the £15 17s, left £11 4s, whereas the present quotation in England was £9 7s. So that if the lead were allowed to go freely into America there was a very good chance of a substantial rise." Then they cheered some more.

It certainly must be a cheering thought to the gentlemen at Washington charged with legislating for the interests of this country, that, though such legislation may take bread out of the mouths of American citizens, yet its effect will be to make wider markets and greater profits for the British mine-owners, whose hopes seem justified by the circumstances.

The "Battle-Born State."

'Twill be thirty years on the 31st of next October since Nevada was admitted into the Union. The admission was done in a hurry, the enabling act being telegraphed from Washington to Carson. The haste was occasioned by the desire to have Nevadans legally participate in the Presidential election which ensued the following week, and in which it was deemed necessary to have Nevada's three electoral votes.

Eastern papers indulge in slurs and sneers concerning Nevada's dwindling population, forgetful of the days when it was the backbone of the North's finances, turning in hundreds of millions of gold and silver. San Francisco, too, owes at least grateful remembrance to the State that enriched so many of its citizens, and so long enabled California to have four United States Senators. But though

the glory of Nevada belongs almost wholly to the past, she has wealth apart from that concealed in her crags. Her area of over 110,000 square miles comprises great tracts that only need irrigation to produce fruitful crops, and while the output may aggregate less in value than the mining yield for many years, yet there is a permanence to the pursuit that will turn the tide of wealth toward that State instead of away from it.

It is a noticeable fact that the finances of Nevada are in better shape to-day than those of any other State in the Union. The irreducible school fund of the State is nearly \$1,800,000. In many of the counties there is more money than is needed in the county treasury, and the mercantile failures make the smallest item in the Dun or Bradstreet lists.

Exports of Gold.

The exports of gold from this country to Europe from January 1st to March 22d have exceeded the imports during the same time by \$5,087,820. The causes of this exportation, says *Rbades' Bankers' Journal* for April, have been in part to pay debts abroad, because it was, owing to the conditions of trade, cheaper for American merchants to remit specie than to buy foreign exchange, but chiefly because there has been a slight premium paid for it by European gold importers. This premium has been paid to supply the gold for investment in the gold bonds of foreign governments—Austria, for instance, desiring to place its financial system upon the gold basis. The government selling the bonds makes a contract with a syndicate of bankers, giving them a certain percentage for commissions and expenses. These bankers find they can afford to give shippers here a portion of this commission for the gold, and thus in reality offer a premium. It is readily seen how exports would take place under these circumstances when the price of foreign exchange would seem to preclude them.

But while these are valid reasons for the export, it seems rather hard to explain why the exportation of gold should continue in the face of such a large excess of our merchandise exported, during the past eight months amounting to \$218,000,000. The truth is that, owing to the defects in the financial system of the United States, gold is made cheaper here than in other countries, and the financial depression has so piled up the reserves in the money centers as to glut our money markets. Our money markets affording no opening for much of this surplus, the banks and others who are looking for safe placement of it, direct their eyes abroad for opportunities in Europe. Silver dollars, silver bullion and paper money will not be taken there, and consequently the gold itself goes whenever wanted. That a still larger amount has not gone is due to the large exportations of merchandise mentioned, and also to the fact that there is no such scramble for gold as is assumed by many. At the best, gold is an expensive thing to handle and to keep. It brings no interest directly; its only purpose is to form the foundation of the financial systems of the civilized nations. Just as little as is requisite for that purpose will be taken and held by any sensible nation.

There is no country to-day from which it is easier for foreign nations to draw gold if they want to than from the United States. The large amount of paper currency redeemable in gold enables any one to obtain the metal from the Treasury whenever there is any profit in doing so. The Bank of England holds the main gold reserve in England, and the Bank of France in France. These banks are in much better condition and employ more means to prevent their gold being drawn out than the United States Treasury can, under present conditions, employ. The banks mentioned raise the discount rate whenever their reserves of gold seem to be liable to too severe drafts. They can thus, to a certain degree, change the relations of business so as to render dealings in gold unprofitable. The United States Treasury, while it has all the features of a bank of issue, has none of the loaning powers of a bank which enable it to control business in a way to protect itself. It must pay out gold whenever demanded, and if the revenues upon which a new supply depends, are reduced, it has no other resource but to borrow. We do not mean to say that the gold for export is taken always necessarily from the Treasury. It is often directly furnished by the banks. But the banks very well know that whenever their supply runs low they can, with their large reserves in paper money, replenish their supplies from the stock in the Treasury.

THE publisher of the *Puget Sound Lumberman* is reported to be in the peculiar business of running a lumber paper, and also in the shingle business, quoting prices at 20 per cent below association rates, thus coming in competition with his advertisers. The result of the experiment will be interesting.

General Mining Notes.

DIRECTOR OF THE MINT PRESTON wants the Carson Mint removed to Denver.

ONE THOUSAND men are prospecting for gold on the eastern slope of the Nicaraguan Andes.

EIGHT THOUSAND tons of gold have been mined throughout the world during the present century.

THE Mayflower Mining Company has put in a bid of \$12,000 for the Kling estate property in Amador City.

THE Monitor and Jim Crow mines, in the Ferguson district, Nevada, have been sold to J. R. Delamar of Idaho for \$150,000.

THE Napa Consolidated Quicksilver Mining Company paid a quarterly dividend of 10 cents per share, or \$10,000, last week.

THE Boise Mining Company will operate a Bucyrus gold-saving machine in the placers of Moore's creek the coming summer.

THE Alaska-Treadwell Mining Company has paid a quarterly dividend, at the rate of 37½ cents per share, amounting to \$75,000.

THE Copper Queen Co. will extend its line from Fairbanks to Benson, Arizona, and thereby acquire adequate transportation facilities.

THE United States Supreme Court has denied the petition asking for a hearing of the Amy-Silversmith and Non-Consolidated mining cases.

MONTANA has produced nearly one-third of the gold, silver, copper and lead in the United States. The mines of the State have yielded over \$400,000,000.

THE Boston and Colorado Smelting Company has decided to rebuild the recently burned smelter at Butte, Mont., with a capacity to heat 150 tons of ore daily.

WHILE drifting in the Hidden Treasure mine at Folsom an old abandoned tunnel was found, the timbers in which were rotten. A cave would carry away the railroad track and a large brick freight depot.

THE antimony ore produced from the mines in Bernice district, Churchill county, Nevada, brings \$50 a ton in this city. It is sold for \$25 a ton on the dump. Ten years ago antimony sold for 30 cents a pound—\$600 a ton.

A NUOGET of tin has been discovered in the mines of North Dondas, Tasmania, estimated to weigh 5400 pounds. The assay of a small piece shows that the large mass of ore contains 67 per cent of metallic tin.

THE Calumet and Hecla Copper Mining Company of Michigan has declared a dividend of \$5 per share, amounting to \$500,000, the largest sum now disbursed in a single dividend by any mine in this country, payable May 15th.

THE Anstin (Nevada) *Reveille* learns that the Jenkins mill at Kennedy is only capable of reducing about six tons of ore in 24 hours; that by the present process the mill is not able to save the gold, and that the tailings assay from \$5.50 to \$10 per ton.

CHARLES J. ELLIS has instituted a suit against Frederick Frankenthal asking the Superior Court to prevent said defendant from disposing of the Gambetta quartz mine in Madera county, alleging that he is the owner of said mine.

ONE HUNDRED AND FIFTY miners in the employ of the Delamar Mining Company at Delamar, Idaho, have gone on strike on account of a reduction of wages from \$3.50 to \$3 a day for miners and of carmen from \$3 to \$2.50 a day. The works are closed down.

THE "Red Oxide" location in White Cloud mining district, Humboldt county, Nevada, is on a heavy outcrop of iron and copper, forming the peak of a lofty mountain. Miners say it is the capping of an extensive copper body which will be encountered at a vertical depth of 400 to 600 feet. Some very poor mining has been done on that property.

THE Boston and Colorado Smelting Company has declared the usual quarterly dividend of 2½ per cent, payable immediately. The extra dividend in April for the past three years is omitted this year because of the business depression in Colorado. This extra dividend was 10 per cent in 1893 and 1891, and 7½ per cent in 1892.

CONGRESSMAN MAYEE is confident that his compromise proposition on the silver question will pass the House, notwithstanding the adverse action of the Coinage Committee. Meyer proposes to get his compromise direct before the House as a substitute to the free-coinage bill. Bland says he does not think the Meyer bill will be germane as a substitute for free silver, owing to the bond feature.

A STATEMENT of the value of the mineral products of Canada for the past year shows an aggregate of \$19,250,000, or \$250,000 less than that of 1892. Nickel heads the list, the output having been 33,392,892 pounds, valued at \$2,078,351. The value of gold was \$927,244; copper, \$875,864; silver, \$321,423. There were mined 3,700,000 tons of coal, valued at \$8,422,269. The quantity of iron ore mined is placed at 124,702 tons, valued at \$298,081.

P. T. FARNEWORTH, general manager of the Horn Silver mine at Frisco, Utah, says he will start at once with the erection of new works to take the place of those destroyed by fire, and a new hoist and a new concentrator will be built, with new and improved machinery. He estimates the cost of the plants at \$125,000, and says that shipments will be resumed from the mine. They expect to ship about 800 or 1000 tons of ore per month.

THE Chicago Gold Mining and Milling Company, with a capital stock of \$200,000, has been incorporated at Baker City, Oregon. The principal office of the company is to be in Baker City, and the following officers and board of directors have been elected: President, W. H. Hackney; secretary and treasurer, J. C. Anstin; general superintendent, L. Durkee; directors, W. H. Hackney, J. C. Austin, P. Basche, J. L. Rand and L. Durkee. The basis of operations of the company will be in Sparta district, Union county, Or., where the company owns a group of nine claims.

A STORY is going the rounds, says the Wahsatch (Utah) *Wave*, about some Midway prospectors, worth repeating. The boys went out to Mercur some time ago to search for gold. They roamed over the hills picking up samples here, there and

everywhere, which they brought home to Midway. In looking over their specimens after arriving at their destination they found one piece that looked much better than the others and sent it to Provo for assay. The returns showed that the rock reached up into the hundreds in both gold and silver. They were so much encouraged that they hitched up and started right back for the new El Dorado. After spending a couple of weeks in a vain endeavor to locate the hidden treasure they again returned to the humble vocation of tilling the soil.

General News Notes.

FOURTEEN FEET of snow fell in Alaska last year.

FIRE destroyed a large part of Challis, Idaho, last Sunday.

THE Wilson tariff bill will not be passed before September, if at all.

THE increase in the public debt for the month of April was \$1,100,971.

THE World's Fair stockholders are to be paid a 10 per cent dividend.

THE Portland, Or., mayor has the appointment of 400 municipal officials.

THE St. Charles hotel, at New Orleans, was burned to the ground last Sunday.

OVER \$5,000,000 in gold was shipped to Europe from New York during the week.

A CHINESE RESTAURANT furnishing 15-cent meals is the latest at Nevada City, Cal.

CRANKS are writing letters to the President, threatening to blow him up with dynamite.

OUT of 1292 answers to letters sent to Kansas farmers asking if farming paid, 1251 answered "no."

THE entire California Congressional delegation are unanimous in favoring the Nicaragua canal.

ALL the unemployed in this State who organized into the "Industrials" have marched eastward.

THE Portland, Or., Commercial Savings Bank, which suspended last July, has resumed business.

SANATOA PAFAR has a bill in the Senate forbidding any one person to own more than 100 acres of land.

LONDON'S industrial exhibition opens to-day. A copy of the famous Ferris wheel is one of the attractions.

A PHILADELPHIA MAN dropped dead at a poker game last Saturday. He held four aces and joy killed him.

THE bonded debt of the Pacific railroads, together with interest due the United States, amounts to \$130,000,000.

THE division of the reward for Chris Evans' capture gives Gard's posse \$3000, and Hall, Witty and Perkins \$2000.

IT is proposed to build an electric railway between New York and Washington that will travel at the rate of 200 miles an hour.

CHEEKEE INDIANS will divide the \$8,000,000 received from the sale of Strip bonds, each man, woman and child getting \$600.

WITH a silver pick President Diaz finished last Sunday the opening from end to end of the seven-mile tunnel out of the Valley of Mexico.

THE People's Home Savings Bank of this city has been declared insolvent. It took nearly a year's time and cost \$92,000 to attain that result.

SENATOR VOORHEES of Indiana swears by all that is high and holy that the income tax will stay in the tariff bill and conjures all and sundry not to forget it.

SOME one with very little to do has figured that there have already been uttered in the debates of the present session of Congress more than 20,000,000 words.

THE American Federated Trades and the Knights of Labor will endeavor to consolidate at a meeting to be held June 11th in some city to be determined upon subsequently.

THE Secretary of State for India, replying to recent Parliamentary questions, said that the statement that the Government intended to reopen the India mints is entirely unfounded.

CAAMP, the Philadelphia shipbuilder, has asked the English Government's permission to bid on the construction of the new British war cruisers, and old England is aghast at Yankee impudence.

THERE are \$455,000,000 in the forty-one savings banks of New York and Brooklyn, held by more than 1,000,000 depositors. The capital of all the national banks in the country is only \$700,000,000.

WILLIAM R. HEARST, of the *Examiner*, is to do away with his Bureau of Claims at Washington, and brings suit against John Wedderburn, who, he says, has run the bureau in debt and failed to render account.

THE statement is made that a damaged silver dollar, of full weight, will bring the owner 43 cents. The officials of the National Bank of Savannah have been told so by the superintendent of the Philadelphia Mint.

GEORGE K. FITCH has filed a bill of revivor praying that a receiver be appointed to take charge of and sell the *Call* and ten days subsequently the *Bulletin* at public auction or at private sale to the highest bidder for cash.

THE twenty-year-old controversy over 178,000 acres of land, valued at \$750,000, claimed by the California Railroad Company and the Oregon Central Company, has been submitted to the United States Circuit Court of appeals for decision.

THE regular monthly statement of the Director of the Mint shows the coinage executed at the United States Mints during the month of April, 1894, to have been as follows: Gold, \$10,184,000; silver, \$554,000; five-cent pieces, \$22,500; total coinage, \$10,750,000.

SEIGNIORAGE may be defined as the profit, exclusive of cost of manufacturing, between the cost of bullion used and the price at which the coin is issued, after deducting the loss of bullion in the process of coinage. Thus, 1000 ounces of silver at say 64 cents per ounce in gold, would be \$640. This will coin 1292 pieces, upon which the seigniorage will be \$652, less the loss of

bullion in the manufacture, say about \$6, making \$646. The cost of manufacture of 1292 pieces is \$39, thus making a net seigniorage of \$607, upon an expenditure of \$640 in gold for 1292 silver dollars.

SEVEN THOUSAND rioters at Cleveland, Ohio, smashed up several manufacturing establishments in that city during the week. The mob was mostly foreigners—Dagoes and Poles—and the sole reason and purpose was a desire to plunder and destroy. The State troops are prepared to check further trouble.

THE big tie-up on the Great Northern is off, and the entire system resumes work. St. Paul, Minneapolis, and the A. R. U., were too much for President Hill. Mutual concessions and arbitrations have raised the blockade, and the 4500 miles of track and the attendant industries will again assume active operations.

THE Treasury statement issued on the 1st shows that during the last month the receipts aggregated \$22,692,364, and the disbursements during the same period \$32,072,838. The receipts for the ten months of the present fiscal year are shown to have been \$245,809,749, and the disbursements \$311,357,196, leaving a deficit for the ten months of \$65,447,447.

THE estimates by the Director of the Mint of the silver product of the United States for 1893 give a total of \$60,000,000, as against \$74,995,000 for 1892. Increases are shown in Alaska, Arizona, California, Colorado, Idaho, North Carolina, South Dakota, Texas and Washington, while in all the other States and Territories the figures show a decrease of production.

THE International Bimetallic Conference began its sessions at London last Wednesday, and is attended by many prominent financiers. The four hundred delegates are unanimous in the desire to maintain the ratio between gold and silver under an international agreement. Arthur Balfour, the Conservative leader in the British House of Commons, declared the best safeguard against impending danger was the remonetization of silver.

COXEY and his 500 "Industrials" marched to the National Capital grounds at Washington, D. C., last Tuesday. CoxeY tried to speak, but was hustled out of the grounds and afterwards arrested. Carl Browne's attempt to make an address resulted in the police taking him to jail. The other detachments of the "army" are scattered in various parts of the country. The Knights of Labor say the railroads must transport Kelly and his men through Iowa.

FISH COMMISSIONER MCMENOC proposes the organization of a State Game and Fish League, which shall comprise in its membership every one who goes fishing or hunting, all to wear a button and that to be a sufficient introduction should strangers meet. The fees are to be \$1 a year. One of the objects of the society outside of fraternity will be to do away with poaching and killing game out of season. It is thought that were the league properly organized it would have a membership of 100,000.

THE wool production of the United States increased from 1860 to 1870 168.81 per cent; from 1870 to 1880, 43.52 per cent; from 1880 to 1890, 18.71 per cent; from 1890 to 1892, 6.52 per cent. The total increase from 1860 to 1892 was 387.84 per cent. Consumption increased, same time, 414.98 per cent. The London Board of Trade estimates the world's production between 1860 and 1889 increased 100 per cent. Wages of 219,132 employees of American woolen industries amount to nearly \$77,000,000 annually. Their work quadruples the value of about \$99,000,000 worth of wool used.

OR the entire population of the United States in 1890, 60 per cent were single, 35 per cent were married and 5 per cent were widowed. Statistics for the Pacific coast are as follows: California—Total, 700,059; single, 455,250; married, 216,029; widowed, 19,222; divorced, 2586; unknown, 6972. Oregon—Total, 181,840; single, 118,827; married, 56,262; divorced, 752; unknown, 1146. Washington—Total, 217,562; single, 146,851; married, 63,538; widowed, 5145; divorced, 761; unknown, 1267. Nevada—Total, 29,214; single, 19,990; married, 8023; widowed, 771; divorced, 166; unknown, 264. Utah—Total, 110,463; single, 72,266; married, 33,823; widowed, 1802; divorced, 214; unknown, 358. Arizona—Total, 36,571; single, 25,972; married, 9536; widowed, 918; divorced, 104; unknown, 41. New Mexico—Total, 83,055; single, 50,985; married, 29,343; widowed, 2479; divorced, 207; unknown, 41.

Personals.

A. WATERS has returned to Nicolaus from Tuttle town.

SUPR. DAOOETT, of the U. S. Mint, is visiting Humboldt county.

B. B. CHANDLER has gone to Umpqua, Or., to oversee operations there.

LIAM, C. E. GILLETTE, C. E., of the Debris Commission, has returned from a visit to El Dorado and Tuolumne counties.

D. A. McDONALD, "Alex Quartz," who was married last week, has gone to Ashland, Or., to superintend some mining property there.

F. M. SPEER, the inventor, has been mysteriously missing for nearly a month, and his friends are unable to account for his disappearance.

J. S. PILLSBURY, the "flour king," was in San Francisco this week. He attributes the low price of wheat to "overproduction and gambling at Chicago."

F. J. CAEREL, a well-known mining man, representative of the Selby Smelting Company of this city, died of heart disease at his room at the Spokane Club last Tuesday night.

GENERAL J. R. WILLIAMSON, a pioneer of Austin, Nevada, committed suicide last Saturday. He had been brooding over hard times, and, it is supposed, committed the deed while laboring under temporary insanity.

MAJOR W. H. HEUER, Government inspector of rivers and mining dams, was here last Friday, says the *Anderson News*. He went to Igo and Ono to look at the restraining dams of the Engles, Gardner and Tom White mines, and reports them all right. Mr. Heuer also went out to the free bridge across the Sacramento and took a look at that. He said that if the Government ordered work commenced on the river above Red Bluff, the first thing that would have to be done would be for the county to put a draw in the bridge.

Water Power and Electric Transmission.

One of the most interesting examples of electric power transmission the country affords is that of the Redlands Electric Light and Power Co., a plan of which is herewith shown. The station of this company is located some seven miles from Redlands on Mill creek, a stream which flows from the Sierra Madre range. A small dam across the main branch of the stream deflects the water into a tunnel 168 feet long, cut through the solid rock, where it flows into a sand box at the head of the pipe line, 75 feet long by 25 feet wide. The pipe line is 7250 feet in length and the total fall 368 feet, involving a loss of head by friction of 28 feet, leaving an effective head of 340 feet. At its lowest stage the stream furnishes water sufficient for 800 h. p., with several times that amount at a maximum.

The wheel plant consists of two pair of double nozzle 30-inch Pelton wheels, each pair having a capacity of 400 h. p., connected direct to the shafts of two 250 K. W. generators, also a 21-inch wheel driving a 50-light 2000 c.p. arc machine and two 11-inch wheels running the exciters. All of the electric machines, as will be observed, are driven by direct connection to the generators and exciter shafts, the wheels being made of a size to give

"After some seven months continuous service, I am able to state that the water-power plant of the Pelton Water Wheel Co. has given us unbounded satisfaction and our installation as a whole is a model one in every respect. Since opening the gates and turning on the water, the wheels have required no repairs nor any other attention than oiling the journal bearings. The differential governors control the wheels perfectly and maintain a uniform speed on the generators under all variations of load, even the extreme changes caused by starting and stopping the 200-horse power synchronous motor at the ice-house 4½ miles away. This is the best device for water-wheel regulation that we know anything of, and, as will be seen, meets the most exacting requirements of electrical service."

This station has not only been a most pronounced success from an engineering, but from a financial standpoint as well, all the power developed being in demand at remunerative rates, so that an increase of the plant is now under consideration.

Chlorination of Gold Ores.

TO THE EDITOR:—The term "chlorination" was coined by the writer and first used in his advertisements in San

gange of the mother lode of California, encased in black graphitic slate, the harrel chlorination requires excessive quantities of sulphuric acid to satisfy the alumina present, before any chlorine gas is available for the gold—a difficulty not experienced with vat chlorination.

The latest chlorination process before us, an Australian invention—Sutton's—also a harrel process, in which chlorine is generated in a revolving generator on the same shaft with the impregnation barrel from salt, hinoxide of manganese and oil of vitriol, is the most revolutionary innovation in chlorination. Mr. Sutton astonishes the old operators by his magic collection of the gold from its centrifuged solution by means of churning with kerosene oil and iron protosulphate and centrifuging the precipitate. His method is free from the drawbacks and objections to acidulation of ore pulp mentioned, and has furthermore the advantage of using chlorine as a gas instead of chlorine water, the former being, as Plattner discovered, a stronger solvent of the gold.

Vat chlorination, as introduced by the writer, still holds its own in California, being the most simple and efficient method on ores adapted to chlorine treatment, free from the expense and trouble of machinery; allowing whatever time is needed for the thorough extraction of the coarser

POWER TRANSMISSION PLANT OF THE REDLANDS ELECTRIC POWER COMPANY.

proper speed under the head available and of capacity required to operate the various machines to which they are attached. By this means, all counter shafts, pulleys and belting are avoided, as also the loss of power and cost of maintenance that their use would involve.

The wheels are located in another compartment separated by a heavy wall, the shafts projecting through this into the generator room, and are supported by wall boxes set in solid masonry. By means of water tight glands and insulated couplings, the electric machinery is thoroughly protected from any dampness that might interfere with perfect insulation.

Provision has been made for the subsequent installation of another generator and arc machine to be driven by separate wheels in the same manner as the others. Pelton differential governors are attached to the wheels, by which means absolute control is obtained under wide and instant variation of load. Two circuits are run from the power house—one to the company's office at Redlands, a distance of seven miles, and from thence distributed over the city for lighting and power purposes; the other circuit extending 4½ miles, operating the plant of the Union Ice Co. These works require 200-horse power, and have been run continuously 24 hours per day for the last six months without interruption or a hitch of any kind.

The hydraulic part of this plant was installed by the Pelton Water Wheel Co. and the electrical machinery by the General Electric Co., it being what is known as the triphase system. The president of the Redlands Electric Light and Power Co.—Mr. H. H. Sinclair—furnishes the following statement as to the operation of this plant:

Francisco papers, when introducing the Plattner chlorine process in California in 1860 in connection with his patented combination apparatus now known as vat chlorination.

In late years many new chlorination processes—the Mears, Newberry-Vautin, Pollock, Rothwell, Thies and Sutton processes, have been presented to the mining public.

They are all substantially modifications of Plattner's chlorine process, based on the principle of extracting the gold from its ore by means of chlorine. As far back as 1870 acidulated bleaching powder to generate chlorine for the Plattner process had been used at Reichenstein, Silesia. See Wagner's Chemical Technology, 1870, page 110.

The Mears, Newberry-Vautin and Pollock processes use chlorine under pressure in revolving harrels, but on Mr. Rothwell's and Thies' authority no better extraction of the gold is obtained with high than atmospheric pressure of chlorine gas.

All the later chlorination processes have adopted the revolving-harrel system, while the old California chlorination process still adheres to the treatment in stationary vats.

The harrel chlorination aims to work large quantities of gold ores daily by a short exposure—of say three hours—to the action of chlorine, but is in consequence limited to the treatment of ores carrying the gold in very fine subdivision.

Gold ores containing hydrated oxide of iron, when treated by the harrel process, have to be subjected to a preliminary roasting, not required for vat chlorination.

Furthermore, on roasted pyrites, concentrated from the

gold, a matter of no small importance in these days of fierce competition.

G. F. DEETKEN.

Auburn, May 1, 1894.

Few Mining Failures.

One thing particularly noticeable in Dun's review of the country's commercial failures, last year, is the small number of mining failures reported. Many silver mines have been temporarily abandoned, but very few of them were sold out by the sheriff or placed in the hands of receivers. In Dun's classification mining failures are put in the manufacturers' class. Idaho had but eight such failures last year, and, if all the concerns had been silver mines, the record would hardly be considered a bad one for the mining industry, except in comparison with the showing made by some of the other silver-producing States and Territories. From Wyoming but one mining failure was reported, from Arizona only one, and from Montana, Nevada and New Mexico none at all. In these six States and Territories there were, according to Dun's report, not more than ten mining firms and companies that collapsed from any cause whatever during the year 1893.

THE Stockton Mail claims that "the price of wool has not gone down, but the price of gold has gone up." This is on a par with the declaration that some time ago appeared on the front door of a defunct Texas bank: "This bank isn't broke; the people are broke. It owes \$75,000; the people owe it \$100,000; when they pay, it will pay." In both cases, whatever the line of reasoning, the facts remain the same.

The Amy-Silversmith Case.

The recent decision of the United States Supreme Court in the Amy and Silversmith Non-Consolidated mining controversy, says the Butte *Inter-Mountain*, has caused more comment among mining men and lawyers than anything that has come from that high tribunal in recent years. The legal profession is nearly unanimous in its belief that the Supreme Court erred and has caused great confusion. A great many letters have been received from Denver appealing to the Montana bar to secure a rehearing of the case. The decision, it is claimed, upsets all practice that has heretofore prevailed. Hon. W. W. Dixon, who is now in Washington, has prepared a very interesting and pungent brief on application for rehearing, that will be read with interest in miolog and legal circles. The salient points of Mr. Dixon's application are here given:

The court says in its opinion that it cannot become a locator for the claimant or relocate his claim and make new side lines or end lines, and yet, with due deference, we submit if that is not just what the court has done in this case. The claimant of the Amy made side and end lines for his location, and the court has converted his side lines into end lines and his end lines into side lines.

Third—By the statute the locator has the right to all veins the top or apex of which is within the surface lines of his location, and it is nowhere provided that to give extralateral rights as to any of these veins the location must be laid in the direction of the course of each or all of such veins or so that all such veins shall depart from the location through the surface end lines. We take it for granted that the court understands in this case that defendant never claimed any right to follow any vein across the Amy surface side line upon its course or strike, but only to follow beyond such side line on its dip a vein of which the Amy had the apex within its boundaries and to the extent only that it had such apex. When the latter right is denied us we are deprived, as we contend, of a privilege the statute expressly gives us by reason of our ownership of the apex of the vein.

Fourth—If, as is said in the opinion, the end lines of the Amy location become its side lines as to the vein in controversy, it would appear as though defendant would have a right to follow this vein on its dip to any distance beyond the surface end lines of the Amy. The result of this would be that in every case where the vein ran as in the case at bar the locator might have 750 feet on each side of the center of the vein or 1500 on one side, although the statute expressly limits him to 300 feet on each side. So he might have a right to go on the dip beyond his surface end lines, although he had himself established them as boundaries, beyond which in no case could he trespass upon an adjoining owner. The practical application of the principle established by this decision will give rise to many contradictions and curious complications which can readily be called to mind, but cannot well be dwelt upon here. We would suggest the question in connection with this point as to where the two end lines of the location would be held to be in case the vein in question passed on its course out of one surface end line and one surface side line, or in this case if the vein passed out the east end line of the Amy instead of the south side line. Under the decision, the north side line of the Amy becomes one end line, but does the east end line continue to be the other end line? If so, we have two end lines at right angles to each other; otherwise we have only one end line, whereas the law certainly requires at least two, and says they must be parallel. The opinion of the court would seem to be that any divergence of the location from the course of the vein, so that the vein departs through one or both side lines, no matter how slight such divergence may be, destroys all extralateral rights on the vein; therefore, if the vein departed across the side line by even so much as a foot at the corner of the location, valuable rights would be lost, whereas, if the locator had happened to fix his end line ten (10) feet short of where he did, the vein would have gone through the end line and all his rights would have been preserved. These matters are suggested, not in any captious or hypocritical spirit, but to call the attention of the court to the nicety of the question involved in this decision and to the importance of placing the rules that are to govern this class of cases upon as sound a basis as possible. It is readily admitted that no theory is free from some difficulties, but it is important to adopt one conforming as nearly as possible to the spirit and intent of the statute.

Fifth—We fear the court underestimates the difficulty, the time and the expense required to determine the actual course of a vein, either before or after location, for a distance of 1500 feet, or even less. It is, in most cases, the work of years. For many hundred feet the strike may be regular, and then it may suddenly turn almost or quite at right angles. If a mine owner has no extralateral rights,

unless his location is laid exactly along the vein, he cannot be safe in following his vein to any great depth or on its dip into an adjoining claim until he has exposed the whole length of the vein and found that it runs through both end lines of his location. If he finds it does not, his work will usually be in vain, for he loses the most valuable right he has. At great expense, perhaps, he has demonstrated the value of an adjoining claim which has the dip of the vein and whose owner has incurred no risk and done no work, and very likely has not the apex of any vein within his boundaries and never would himself have found the vein upon his dip beneath his own surface.

The importance of the question involved in this case in all mining communities cannot well be overestimated. This is not, of course, any reason for departing from the legal construction of the statute, but it is a reason for careful and thorough investigation and consideration of the subject.

It seems to us that, practically applied, the rule laid down in the decision in this case will result in doing away with all extralateral rights on veins, although such rights are expressly given by the statute and are among the most valuable pertaining to lode claims. Locations will be practically confined on all sides by vertical planes.

We have mentioned here only some of the grounds upon which we think we are entitled to a rehearing, but others will readily suggest themselves.

It may be remarked that the question here relates to a peculiar branch of the law, with which some of the members of the court are necessarily not very familiar, and that an oral argument, which has not been had heretofore, on the part of the defendant, might possibly be of some assistance to the court. We have been induced to ask this rehearing, not only for the interest of the defendant in the case at bar, but by the request of many mine owners and their representatives, who think their rights are injuriously affected by the decision of the court, and who hope that an opportunity may be afforded for the most possible, careful consideration of the question involved before it is finally decided by this high tribunal, from which there is no appeal.

Relation of Engineering to Civilization.

It is unfortunate for the engineer, says Prof. Hutton in the "School of Mines Quarterly," that his work, fundamental to so much which makes the comfort and civilization of the day, should be concealed and disregarded simply because it underlies. Without the engineer, life in cities would be impossible, where there was no gas, no water supply, no sewage, no food supply except by wagons, no motive power but human muscles. There would be a patrician class served by a class of slaves, and that great, powerful, conscientious, reliable middle class, which makes a nation great and prosperous, would be unknown. Even in the Columbian Exposition, which has been considered the flower and example of what this century has done in the way of artistic culture and industrial progress, beneath the architectural beauty and genius of conception there lies concealed and embedded many weary months of a burning of midnight oil, and of the expert skill of the engineering toiler, in the preparation of the ground and the erection of the structures. Those who delighted in the luminous fountains by night and the marvelous effect of illuminations and the ghost-like flitting of the launches on the lagoons gave, probably, hardly a thought to the pulsing, pumping engine and to the whirling dynamo, over whose production the engineer had presided, and over whose regular march a faithful, conscientious but unseen toiler was watching with a ceaseless attention, and he also as an engineer. These things make a nation great and prosperous, a fertile land, a reverent, painstaking, capable body of professional engineers.

Separating Fine Gold.

What is claimed to be the most advantageous process for the separation of fine gold in placers comes from Montana. It is a dry process, says the *Sun*, designed especially for localities distant from sufficient water for other methods, the ore or gravel being run through a crusher or steam drier, after which it is dumped into the hopper of the separator. Dropping from this, it strikes a powerful blast of air, which carries it between two sets of slowly revolving copper cylinders coated with one-sixteenth of an inch of mercury.

These cylinders are placed in two lines of three each, one above the other, so that the dust, driven by the air blast, passes between them in a wave-like line. The ore first strikes a cylinder similar to the others, but revolves in an opposite direction, which catches the coarser gold and the nuggets. Then, passing between the other cylinders, all the gold is caught, however fine, and the waste is carried by the air blast to a conveyor, which bears it away. The mercury on the cylinders is constantly renewed, so that a fresh surface is always presented; and it is asserted that

the process has been subjected to such various tests, and so successfully, as to demonstrate its peculiar adaptability to the class of work in question.

Electricity's Practical Uses.

The use of electricity for household purposes has hardly got beyond the experimental stage, save in the department of lighting; but enough has been done to show what a transformation may be worked by its aid when it will be possible to have houses heated by it. Then the mere turning on of the switch will suffice; and the current, passing through a suitable heater, which may be as ornamental as means and taste permit, or, if desired, entirely concealed, will do the rest, superseding fires, with all their attendant trouble, smoke and dust. With regard to cooking, there are numerous appliances already devised, and only waiting for the cheapening of the current to be widely taken advantage of. Each cooking utensil, being constructed with the heating coil as part of it, is its own stove; and the whole array of pots and pans need only to have the connection made, and the cooking can go under the most perfect control. Some of the possible arrangements even appear to put a premium on laziness, for, with the food put in the cooking utensils at night, and the necessary connections made, the turning of a switch in the morning in the bedroom starts the cooking of the breakfast. The heating powers of the electric current are also turned to account for raising to the desired temperature hand-stamps, branding irons and the like; while in large laundries electrically heated irons have been found very economical, as they maintain for hours at a time the exact amount of heat suitable for the work, thus saving the ironers much time and trouble.

Medical science has called electricity to its assistance in many ways. Various surgical instruments are heated by it, and the use of very small incandescent lamps, which give out practically no heat, permits more extended examination of the internal parts than is possible in any other way. The use of the microphone has revealed sounds in the heart, lungs and other organs which have hitherto escaped the most sensitive ear using the ordinary instruments. In Russia a lady was saved from premature burial by means of a microphone placed over her heart, which enabled a medical man to detect a faint beat which had escaped the ordinary tests. Another recent development is the use of electricity as a local anæsthetic. Painless operations have been conducted under its influence, and similar applications with suitable apparatus have induced cessation of pain in acute *tic douloureux*. Remarkable cures have also been obtained in such painful maladies as lumbago and rheumatism by simply pressing a small, specially shaped incandescent lamp on the skin over the seat of the pain. It has been found that sufferers from "shaking paralysis" are much better after a rough railway journey; and the late Dr. Charcot, of the Salpêtrière, Paris, the famous specialist in nervous diseases, applied this principle in the construction of a bed, to which a rapid vibratory movement is given by means of electricity, and this shaking, which to a person in good health would be intolerable, proves quite enjoyable to the paralytic subject, who appears to be refreshed by it. Another French physician has devised a vibrating helmet for the cure of nervous headache. An American inventor has brought out a rocking chair actuated by electricity, and the sitter can at the same time receive gentle currents by grasping metal handles or by resting the bare feet on metal pedals.

A patent has been taken out for a mechanical pick-pocket and coat-thief detector—an electrical apparatus which automatically rings an alarm bell when the bearer's personal property is tampered with. Another inventive genius so combined electricity and photography as to secure a flash-light photograph of thieves at work in his office. When they opened a glass case they completed an electric circuit which exposed the camera and simultaneously kindled the flash light, to the great alarm of the depredators. Electricity has further been used in the industrial process of engraving, bleaching, dyeing, the reduction of ores and the purification of metals. Mainly by its aid aluminum can now be produced at a price which is no longer prohibitive. An electric ventilator has been designed for supplying buildings with fresh air, cold or warm, as may be desired. An electric motor sets the ventilator revolving, and the revolution sucks cool air in. When warm air is desired a current of electricity is sent into a network of fine wire, through which the air must pass, heating the wires, and these impart their heat to the air. What should prove a most useful industrial development is the application of electricity to the cleansing and preservation of boilers. The method employed is the sending of currents periodically through the shell of the boiler. By this means the scale formed on the shell and tubes is disintegrated and easily removed.

ONE of the deepest holes, made artificially, in the world, is the one sunk at Parvchowitz, in western Siberia. It has a depth of 6568 feet, and a diameter of 2.75 inches. Work has been stopped temporarily, in order to lower sensitive thermometers into the well; but eventually it is proposed to go down 8000 feet.

The Cornish Tin Streams.

The Cornish tin streamer is by no means a seeker after the ore which is known to mineralogists as "stream tin." He is an altogether modern invention, and depends upon the charity of the big mines, as one may say, for his subsistence, for the ore produced in these mines contains for the most part only a very small proportion of stannic oxide. It is first of all broken by the stone-crusher—a ghastly instrument which reminds you of a giant eating hard biscuit very greedily. Then it is taken to the "floors"—great sheds, open at the sides, and with cobbled floors—and broken yet smaller by girls—"bal maldens," as they call themselves. Next, the stone is fed to the "stamps"—huge iron hammers, which work night and day, and fill the surrounding country with a sound resembling that of a distant and angry sea. Here the stuff is reduced to a powder, and a stream of water washes it out into long trenches in front of the stamps. The lighter portion of the ore is thus partly removed, and though, as will be seen, the process of purification is a complicated one, it consists entirely of various applications of the principle that water, running over a sand made up of various constituents, will gradually eliminate the less weighty components. The concern of the tin streamer lies with this lighter portion which is carried away from the mine.

It is currently asserted that the loss of tin in the Cornish mines is proportionately less than in the dressing of gold ores. Nevertheless, the sand which is carried away with the waste water from the mines is by no means worthless. There is much hematite in tin stuff, and thus everything about the mines is stained a dull red. This is true of the water which has been used to wash the tin. It runs away from the mines, and small individual streams unite in the valleys to form what is known as "the Red river." Many a tourist skirting the Cornish cliffs must now and again have seen the sea incarnadined over a tract extending for many miles. And from their sources below the mines, right down to the very beaches, the tin streamers will be found at work along all the red rivers. First of all, the water is turned aside from its channel and made to run through huge ponds. Sometimes they are 100 yards long, and their banks—built of furze-faggots and slime—are 15 to 20 feet in height. In these the water gradually deposits, in the

form of a red slime, the first portion of its burden. There may be a dozen of the ponds at a single works, and the flow of the water is only stopped when any particular one of them is almost filled with the deposited slime. This is then worked up with water, which carries it on to the "rag frames." Briefly, the rag frame is a slanting wooden table over which the slime-laden water is made to flow. A deposit of slime forms, and the water flows off by a wooden gutter. Presently a lever is lifted with double effect. The first gutter is shut off and another opened, and the frame is suddenly flushed with clean water, whereby the deposit which has formed upon it is carried away through this second gutter in certain ponds, called covers, where it is allowed to settle. Out of these covers the slime is presently conveyed over another set of frames, which are known as "cleaner frames." In the first stage the work is overlooked by little boys. Here, however, it is in the hands of girls and women, who wear big white aprons and sun-honnetts so closed that their faces are hardly to be seen. And some of them are pretty. The slime-laden water still flows over the frames, and the "maldens" carry long-handled and very long-haired brushes, with which they spread the slime abroad and expose the whole deposit to the action of the water. Thus a further separation is effected, and the slime is carried on to yet another set of covers. The girls who are employed at this work are at it all the year through for about ten hours a day, and they are absolutely without shelter; yet most of the girls in mining villages prefer this life to that of the domestic servant. Indeed, if there were frequent frosts, tin streaming would be almost impossible, for

first plays havoc with the frames unless your night-watchers are very much upon the alert indeed. When the water from the cleaner frames has deposited so much slime as suffices to fill one of the covers, it is made to run elsewhere. The slime is then taken away in wheelbarrows to the "buddles." These are of varied forms, and are, in fact, only another method of applying the principle of the frames. The simplest form of huddle is merely a gutter down which the slime-laden water runs, to fall presently into a circular pit. An exit is provided for the water at the side of the pit; the sand or slime remains behind in a circular deposit, the heavier particles being at the center, the lighter at the circumference. When the pit is almost full the water is stopped. A man skilled in such judgments takes a shovel and marks three rings upon the pile; the outer layer is thrown away, and the other two are fed by means of water to the other buddles. But this rudimentary form is only used in one particular instance. Commoner is a slender-spoke wheel revolving in a plane parallel to the bottom of the circular pit. Some of the spokes are wooden gutters; others are merely poles, from each of which a long brush, fitted with very soft hairs, is suspended by a couple of strings. At the axle of the wheel is a circular cup out of which the gutters open. The slime is placed in a wooden trough, where water trickles over

and buddles. The streamers, therefore, have learnt of late years to raise the level of the river bed by means of a board stretched across it. The sand is thus arrested, and the water to some extent removes the lighter particles. Presently the water is turned off into another course, and the sand is thrown out upon the banks. As it is wanted it is conveyed to the pulverizers. These are great revolving cylinders, which contain a large amount of loose scrap iron. The sand is passed into them by a current of water, and they are so devised that it can only find its way out when it has been finely powdered. And it is the sand which issues from these pulverizers which is treated in the first place by the rudimentary huddle described above. Afterwards that part which is not rejected goes through pretty much the same process as the stuff which gets deposited in the slime pits. These tin streams return a very large quantity of tin every year. It would seem that any number of them may subsist upon the same stretch of the Red river. And even when the water gains the sea it is by no means wholly deprived of its tin.

Mt. Shasta.

The approach of the outing season gives keen zest to striking portrayals of the gems of natural scenery. In

this list may surely be placed the engraving upon this page, page, notable as a new view of one of our grandest mountains—quite different from the earlier portraits of this grand uplift of earth-crust which have already appeared in our columns.

Mt. Shasta has been appropriately termed the keystone of the arch formed by the great incurving mountain chains of California, the Coast Range and Sierra Nevada. Though the great floor of the Sacramento valley terminates about on the southern boundary of Shasta county, in a foothill region half-circular in shape, there is beyond this the upper valley and its many arms with their inclosing hills and mountains, forming a country rich and picturesque, which extends northward many miles before the higher mountains close in and place the crown of eternal snow aloft on Shasta's brow, 14,440 feet above the level of the sea.

It has been frequently remarked of late that the great snow-covered mountain, through the dissemination of engravings of it reproduced from the masterpieces of the

artists, has really given distant people the impression that northern California was an arctic region and central California must therefore be semi-arctic. Such conclusions are very erroneous. The towering Alps do not lead to a misconception of sunny Italy, nor should Shasta reflect a chill, even in thought, upon the genial regions which owe their winterless climate in part to the protection afforded by his massive form and by the ranges which inarch their ridges on either side to support his pedestal. A recent writer has commented upon the majesty and beneficence of Mt. Shasta as follows:

"Of all American mountains it has the most sovereign look. It leans on no other height; it associates with no other mountain; it builds its own pedestal in the valley, and never drops its icy crown. It is a glory in itself. It seizes the clouds with icy arms and compresses them until their contents are dropped upon the thirsty fields below; from its base the Sacramento starts on its way to the ocean; despite its frowns, it is a merciful agent to mankind, and in the minds of those who see it in all its power and splendor, a picture is painted which will last as long as the gift to admire anything magnificent is left."

Of late years Mt. Shasta has been brought very near to his admirers by the overland railway which passes near him. Accessibility has also made the Shasta region popular as an outing resort. Formerly only the persistent and venturesome penetrated thither, but now the building of a great hotel and the abundance of more modest accommodations brings a hundred to Shasta where one went before.

GUNPOWDER was first employed in blasting in the Hartz mountains about 1120, and was denounced as sorcery.

MOUNT SHASTA—FROM A RECENT PHOTOGRAPH.

Scientific Progress.

Edison's Kinetograph.

The latest wonder of photography is the kinetograph, the marvelous device with which Mr. Edison has accomplished the feat of recording and reproducing motion. It has long been the distinction of the pictorial or plastic arts that they represent form only, but, as the present generation may say of a great many things, we have changed all that. Mr. Edison accomplishes this wonderful result by taking an unbroken series of photographs at the rate of 46 a second, giving pictures of the most agile acrobatic feats so closely following each other that hardly any difference can be detected between any one and the next. When the pictures are made to pass before the eye at the same rate of speed they blend into each other so perfectly that the motions of the person photographed can be seen with great distinctness. Many revelations were at once made by the application of this instrument, which almost equals in importance the discoveries from instantaneous photography, as for instance the fact that in turning a somersault on the hands there is a place where both hands and feet are off the ground at once, although the acrobats had been quite unconscious of the fact.

The chief importance of the invention, however, is in connection with the kinetoscope, as Mr. Edison calls his reproducing apparatus. Its practical uses seem almost unlimited. With the co-operation of the phonograph the words and gestures of a great actor can be handed down to a glorious immortality. Generations yet unborn may hear and see the tragic power of Bernhardt and Duse, of the kaleidoscopic gyrations of the ballet queens of our day. Every one may transform his house into a parlor theater where one may see through a peephole and hear through a funnel the plays of Shakespeare and the operas of Wagner by the simple pressing of a button. Nay, more, if the predictions of such scientists as Professor Houston come true, it will not be long before we have a real telescope which is something more than a spyglass, and will enable us to see as far as we can telephone. Rapid progress has been made in this direction since the discovery of the singular qualities of selenium, which alters its conductivity with varying conditions of light and shade, and Edison, Morse, Le Poutois, Johnson and Amstutz have met with such remarkable results in transmitting light through a wire that many conservative scientists concede the possibility of the electrical transmission of pictures. When that is accomplished we shall be able to talk with our friends a thousand miles away, and at the same time watch the play of their features. Admirers of football in all parts of the country may enjoy the game as it proceeds, kinetoscopic images of each play being flashed on a stereopticon screen. All this sounds incredible enough, but no more so than did the steam engine or the telephone to the people who first heard of them.

Photographing the Clouds.

The poetry of the skies seems to have been caught in the latest specimens of H. Angot's new method of photographing clouds. The blue of the sky, as a rule, sets strongly on the sensitive plate as the white of clouds, and hence a resort to artifice is necessary to obtain clear pictures. When the sun is hidden by the clouds, they come out very well in the photograph; but for the best results a dilute pyrodeveloper and a few drops of bromide of potassium solution should be employed, and the development should be effected slowly. This method, however, does not answer in the case of cirrus clouds, which are composed of snow crystals, and are the most interesting in a picture. Such clouds come out well in

photographs taken on the top of a high mountain, and Prof. Riggenbach has even succeeded in taking them from low levels by warding off most of the blue light of the sky, which is polarized, with a Nicol prism, or black glass inclined at an angle of 55 degrees in front of the lens of the camera.

Angot's method, however, is greatly superior to this, and consists in placing a screen of colored glass transmitting only the yellow and green, and stopping the blue and violet rays, in front of the camera. Orthochromatic or Isochromatic plates must be used, as they are very sensitive to the yellow and green rays from clouds. The best screen is formed of two parallel panes of glass five or seven millimeters apart, and having the space between filled with an almost saturated solution of bichromate of potash to which a few drops of hydrochloric or sulphuric acid have been added.

A BRIDGE RAIL, in the hollow of which telegraph wires, and even a small water pipe, can be laid, has been designed by Herr G. Lichtenfelder. It is calculated that the invention will be of special use in mines, as signaling conductors may thus be brought up to the face of a heading concurrently with the rails, and also the small pipe for leading water with which to keep cool the points of rock drills and clear out the debris from the holes, while such wires and pipes are, at the same time, effectually protected from injury in the event of portions of the roof falling, etc.

ONE objection to transmitting power in the form of steam for a long distance is that a pipe is apt to radiate heat so rapidly that the energy is quickly lost. Eckley B. Cox recently told the American Society of Mechanical Engineers, though, of a case where steam was delivered 4500 feet away from the boiler plant and used effectively. The pipe was conveyed in a trough made by nailing two boards together at right angles, and covered by a similar one, the intervening space being filled in with asbestos.

THE plot chart of the North Atlantic ocean, issued by the United States Hydrographic Office, has long been a valuable resource of the mariner for information about winds and currents, icebergs, floating wrecks, probable weather and other important matters. A similar one has now been issued for the North Pacific. This highly commendable experiment needs Congressional aid in order to be continued, but the growing importance of Pacific commerce fully justifies this enterprise.

ONE serious difficulty in the way of using excessively high steam pressures is that the attendant heat renders lubrication uncertain and unsatisfactory. To substitute graphite for oil in such cases would afford relief. Hence the value of a device lately invented for automatically feeding graphite to a steam engine cylinder. The material is first pulverized and then discharged in a dry powder at a rate easily regulated from a cup on the cylinder.

By the alloy of iron and nickel a new metal has been produced that will sustain a pressure of 15,000 atmospheres. It has been named Krupp metal, and is intended, says *L'Echo des Mines*, to be used for ordnance firing heavy charges of dynamite.

A CANTILEVER BRIDGE will be built at New Orleans for the Southern Pacific road, with one central span of 1070 feet, and two 608-foot anchor spans. The channel span will be the longest bridge truss in the world except that over the Frith of Forth.

BOOKS AND PAPERS, printed with white ink on green paper, is what Dr. Fleming Carrow, of Michigan University, thinks we ought to seek as the best possible provision for easy reading.

Van Drake & Taylor, MACHINISTS

AND MECHANICAL ENGINEERS

523 & 525 Mission St., San Francisco.

SPUR AND BEVEL GEARS cut to order. PATENT MODELS and Experimental Machinery of all kinds. SHAFTING, PULLEYS and BOXES. ENGINES and BOILERS.

DRAWINGS, PLANS and SPECIFICATIONS made for new machinery. JOBBING of every description promptly attended to. FINE WORKMANSHIP GUARANTEED. Also Pacific Coast Agents for the SHARPLES CREAM SEPARATORS.

Adamantine Shoes and Dies

—AND— CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill supplies.

Stamp Die.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for packing on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clock changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clock cannot be changed under water. The self-tightening and self-lubricating stuffing box and new bucket save as much expense of dripping extra pumps.

WM. NANCE, Grass Valley, Nevada County, California.

PIONEER REDUCTION CO.,

NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ores or concentrates.

Address all communications to

PIONEER REDUCTION COMPANY, NEVADA CITY, CALIF.

UNION IRON WORKS, SACRAMENTO.....CALIFORNIA.

ROOT, NEILSON & CO.

—MANUFACTURERS OF—

STEAM ENGINES, BOILERS

And all kinds of

MACHINERY FOR MINING PURPOSES.

FLOURING MILLS, SAW MILLS AND QUARTZ MILLS.

Machinery constructed, fitted up and repaired.

Front St., bet. N and O, Sacramento, Cal.

W. H. BIRCH & CO.

(INCORPORATED.)

MANUFACTURERS OF

Passenger and Freight Elevators, Improved Steam Pumps, Improved Corliss Engines, Mining Machinery, Cable Railway Machinery.

119 BEALE ST., - SAN FRANCISCO.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 80 cents additional per volume.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weir; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hardy-gurds, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

Mechanical Progress.

Recent Air-Brake Tests.

Great things are already done by the best air brakes now in use; but that persistent and accomplished inventor, George H. Westinghouse, has long been studying how to secure even better results—such efforts being rendered necessary by the steadily increased speed and weight of our fast American express trains. An average velocity of 50 miles an hour for several hours means, as every one knows, an occasional lessening of speed to 20 or 30 at curves and bridges, besides stops, and hence occasional increases on level, straight track to the rate of 60, 70, 80 or even 90 miles an hour. If necessity arises, how can trains under these latter conditions be quickly and safely stopped? Obviously, mere pressure of the brake will not meet the requirements. Beyond a certain limit the wheels will cease to rotate, and then will slide; and this will not check progress so effectually as a pressure low enough to just fail of stopping rotation. However, it has long been known that more pressure may be used before the wheels will slide if the train be running at very high speed than at a moderate one; and Mr. Westinghouse has sought to utilize that fact by providing for gradually diminishing the pressure. This would enable him to apply the brakes more vigorously for the first few seconds than has been deemed advisable hitherto. For the present practice is such that the brake remains set at a uniform pressure, whatever that may be, until released.

Two trains were run side by side on parallel tracks of the Pennsylvania road a few days ago for testing Mr. Westinghouse's new plan. On one he carried not only increased pressure in the train pipe and larger air cylinders, under the cars, but also a special pressure-releasing valve in connection with the existing "quick-action triple valves." The locomotive was also provided with brakes for the small forward wheels as well as for the drivers. On the other train increased pressure was the main departure from usage. The two engines kept exactly together, and the brakes were set simultaneously by "tripping" devices placed on the track. Owing to bad weather, unworn brake shoes and some other influences, the tests were not as satisfactory as had been hoped. But experts find in the result indications that the new attachments possess great value.

A New Fuel.

The following is the method of manufacturing petroleum bricks for fuel:

Mix one liter of petroleum, 150 grams triturated soap, 10 per cent of resin and 333 grams of caustic soda. Heat this mixture, being careful to stir it well meantime, until solidification commences—say about 40 minutes. If the mixture should tend to boil over, pour in a few more drops of the soda, and continue to stir until solidification has sufficiently progressed; then pour the semi-fluid material into molds to form the bricks, and place these in a hot room or drying place for 10 or 15 minutes; then remove them and let them cool. In a few hours they can be used as fuel.

To the three elements, which constitute the mixture, Mr. Mastracci recommends the addition of 20 per cent of sawdust and 20 per cent of clay or sand, which makes the bricks more solid and less expensive. Trials of these bricks as fuel have been made at Marseilles on several tugs, and it has been found that, weight for weight, they develop three times as much heat as the ordinary coal brick, and leave no ashes.

It is expected, with some slight changes in the furnaces, to arrive at still more perfect results, not only in the increased heat, but in the entire suppression of smoke, and on the most economical basis, one kilogram

of the solidified material being equal to four kilograms of coal. These experiments seem to be very interesting, and it is quite easy to understand that there is a double advantage in using such fuel on steamers, as they economize in both space and cost.

Rolling Thin Plates.

The record for rolling thin sheets of iron has again been broken, this time in Swansea, Wales, and the process is thus described in a local paper: "The iron from which the sheet was rolled was worked in a finery with charcoal and the usual blast, afterward taken to the hammer to be formed into a regular flat bottom, thence conveyed to the balling furnace, and, when sufficiently heated, taken up, the rolls lengthened, and cut by shears into proper lengths, piled up and transferred to the balling furnace again. When heated, it was passed through the rolls, back again into the balling furnace, and, when duly brought to the proper pitch, taken to the rolls and made into a thorough good bar.

"Subsequently, at the tin mills, it was rolled till it was supposed to be thinner than 23 grains, afterward passed through the cold rolls to insure the necessary polish, the result being the thinnest sheet of iron ever rolled—that is, the sheet was $10 \times 5 \frac{1}{2}$ inches in surface, of only 20 grains weight, which, being brought to the standard of $8 \times 5 \frac{1}{2}$ inches, or 44 surface inches, is but 16 grains, or 30 per cent less than previous attempts, at least 4800 being required to make one inch in thickness."

A Long-Sought Material.

The production of a new glass having the valuable property of supporting sudden variations of temperature has been announced by two German chemists, Winkelmann and Schott. Retorts and other laboratory utensils made of this glass could be exposed without any precaution to the flame of a Bunsen burner or even of a blowpipe. This means, to the chemist at least, a great economy, for much heat is lost by the ordinary process of interposing wire gauze between the flame and the utensil, and it is claimed that liquids can be heated in the new glass with less than half the time and gas necessary by the usual method.

Floor-Washing Machine.

A floor-washing machine has been recently invented. The mechanism consists of a main frame, with suitable driving wheels, driving an endless belt provided with a series of flaps, a water tank delivering upon the belt, which is also engaged by wringing rollers, beneath which is supported a dirty water tank. The flaps absorb the water and bring a large rubber surface to bear on the floor as they are carried beneath the roller, the belt and its flaps then passing between the wringing rollers and the machine being used by simply pushing it across the floor, after the clean water pipe has been opened.

Cart Before the Horse.

Putting the cart before the horse is no longer a mere conception. In France it is now an accomplished fact. An inventor has gotten up a street car or omnibus, not drawn, but driven with gearing from a treadmill attached to the gear of the vehicle and supported on wheels. The horse, therefore, rides while he works.

ANNUNCIATORS, indicating the name of the next station, are in use on the Metropolitan and District suburban roads in and near London. They are set, after leaving a station, by pulling a cord. One official controls the apparatus in all the cars of a train simultaneously. This method of imparting information is an improvement on the one now in general use, of bawling out the names more or less indistinctly.

Electric Progress.

Electricity in Incubation.

Electricity has found a new outlet in Pittsburg in the line of incubation. In one of the prominent business buildings a very crude arrangement has been used to hatch eggs and has given very good results, fully 90 per cent of the fertile eggs resulting in lively, well-developed chicks. The apparatus consists of a small box, in the lower part of which is a drawer lined with cotton, where the eggs are placed. Above them two incandescent lamps of 16-candle power are suspended, and the steady heat radiating from these globules maintains the necessary temperature of 100 to 103 degrees F., which is indicated by a thermometer placed among the eggs. The minor details of moisture and the occasional turning of the eggs were observed as in the ordinary incubation. The chicks are thriving, and a new set of eggs is being treated, about half of which are goose eggs. The scheme is susceptible of considerable development from this crude beginning, as a resistance box instead of the lamps would be more effective and more economical. The commercial aspect of the question remains to be shown.

Switching by an Electric Capstan.

An expert in railway matters declares that the day is not far distant when the switching engine will be entirely done away with, its place being taken by the electric capstan. The latter is already in use to a certain extent on some of the Pennsylvania lines. The motor, which actuates the capstan by means of gearing, runs at the rate of some 1200 revolutions a minute; and the gearing, motor and switch of the capstan are all combined in a water-tight iron case, the top of which comes flush with the ground. There is a cover to it which is readily removable, so as to give easy access to the motor for oiling and cleaning. The wires containing the current for the motor are carried through an iron pipe below the surface of the ground, and the switch for starting and stopping the motor is operated readily by the foot of the attendant in charge of the capstan.

Wind Power and Electricity.

Prof. James Blyth, who has been experimenting in the utilization of wind power for the generation of currents, has devised a new system. To four strong arms, each about 26 feet long, he attached semi-cylindrical boxes, the opening of each box being 10x6 feet. The vertical shaft is a long rod of iron five inches in diameter. At the lower end it carries a massive pit wheel, which actuates a train of gearing, and drives a fly-wheel six feet in diameter. With a fair wind speed it gives four electrical horse power, and it works very satisfactorily in a strong gale.

THE arc lamp is yet to be touched up to more perfectly uniform action; the glow lamp is to be cheapened; alternating current motors are to be perfected; electro-metallurgy is to be fostered and brought more generally into commercial usefulness; condenser railways must be attained; storage batteries or gas batteries of a permanent type are to be designed; long-distance transmission must come; and a host of other kindred tasks remain. We are but on the threshold of the electrical age.—*Electrical Review*.

THE *L'Electricien*, Paris, gives the following pedigree of a word which has attained importance in electrical phraseology: Most persons who use the word "trolley" probably do not know the origin of this term or why this term was given to that apparatus by which the electricity is conveyed from an aerial wire. Twenty years ago the word was used to designate "a form of truck which can be tilted for carrying railroad material or the like." This is the only defini-

tion of the word in Webster's dictionary of the edition of 1848. In the edition of 1892 of the same work three other definitions are added: 1. "A narrow cart that is pushed by hand or drawn by an animal." It is noted that this meaning of the word is in use in England, not in the United States. 2. "A truck from which the load is suspended on some kinds of cranes." This meaning is technical according to Webster, and employed only in speaking of machinery. 3. "(Electric Railway.) A truck which travels along the fixed conductors and forms a means of connection between them and a railway car. It is easy to see how the primitive form of the electric trolley, which travels upon the wires, came to receive its name from its resemblance to other types of trolley; and the name, having been immediately given to this primitive form, was naturally retained when the method of connection was changed from a little truck moving on the wire to a mast having at its end a wheel pressing on the lower surface of the wire.

THE steamer Faraday recently left London with a portion of the new cable of the Commercial Cable Company, which is to be laid from Waterville on Ballingbegs bay, coast of Ireland, to Nova Scotia. The Faraday is not large enough to stow the entire cable, which will be 2000 miles long. The process of laying it will include the dropping of 400 miles of cable this side of the Atlantic, then the placing of another hundred miles on the other side, and finally the picking up of both portions with the main part. The manufacturers guarantee the Commercial Cable Company that this cable will afford 33½ per cent improvement in speed over any cable the company now has in use. This means that 30 words a minute may be sent.

AN interesting point in law was developed in New York city recently. A club rented a house and secured a reduction in the rental in consideration of making some improvements, among which was the introduction of electric fixtures and wiring. The lease of the premises expired, and the club deciding to move, proceeded to take away the electric fixtures. The landlord protested without avail, and finally secured an injunction from Judge Bookstaver restraining the club from removing the fixtures.—*Electrical Review*.

THE first link in the chain of electric railways which will eventually connect New York and Philadelphia is now well under way. The Philadelphia division, between Bristol and Trenton, 34 miles in length, has been surveyed, and that section alone will include a mile of bridgework. The contracts for construction, it is said, will soon be let, and the work will be pushed to an early completion.

AMONG the many experiments lately made for utilizing the rise and fall of the tides as motive power, one is reported to have been tried on the coast of Cheshire, where power for driving a dynamo and lighting a house by electricity has been supplied by a tidal mill of about four-horse power.

THE *Electrical Review* says that Egyptologists have found unmistakable evidence of wire communication between some of the temples of the earlier Egyptian dynasties, but whether these served a telegraphic, telephonic or other purpose is not stated.

ONE of the electric launches that were employed on the lagoons at the Columbian Exposition in Chicago is now running on the Grand Canal in Venice, and is so much liked that it is predicted that the "gay gondolier" will have to go.

ELECTRIC LOCOMOTIVES are proving themselves to be well adapted for use in coal and other mines, and they now furnish motive power for hauling cars in about 30 mines in the United States.

Practical Information.

A Great Jetty.

"The great jetty at the mouth of the Columbia river, in Oregon," says the *Railway Review*, "is the largest and most important one ever constructed, and has the still greater distinction of having been made for 25 per cent less than the estimated cost. The work, we need hardly say, was done by the Government engineers and without contracts. The work is more than four miles long, 15 feet wide on top, and has consumed 6000 piles that were inserted mainly by water jets, a few blows being given at the end of the sinking with a hammer of three tons weight. The estimate for the work was \$3,710,000, and the cost will be one-fourth less. The work is now nearly completed, and has accomplished fully what was intended, giving passage over the great bar for vessels of any draught. The depth of water alongside the work has been increased from 6 to 20 feet in some places, and 4000 acres of area have been raised above the water. The Columbia is 1000 miles long, the only large river on the Pacific Coast, and forms the only safe harbor between Seattle and Puget sound, 600 miles."

Branding Ice.

A novel idea has been patented by Van der Weyde, by whose inventive ingenuity the electric light was first successfully applied to portrait photography, for the purpose of securing pure ice for table use. The invention is based on the fact that two smooth surfaces of freshly cut ice, when brought into contact at a temperature below the freezing point, will unite so firmly that the junction between the parts will be as strong as any other portion of the combined mass. Subjected to a higher temperature, however, the junction is the first to yield to a blow or pressure, and the ice easily breaks into the original pieces. Utilizing this property, Mr. Van der Weyde casts blocks of ice into small cubes, which are stamped with a star or other trademark. These cubes are joined into a larger cube, say of 16 or of 32 pounds weight, and so sent out for use. The trademark is a guarantee that the ice is perfectly pure, and the small cubes weigh only half an ounce—a most convenient size.

Shepherds in Italy.

The first annual report of the United States Commissioner of Labor thus portrays the conditions, wages, etc., of shepherds in Italy:

"Condition—Lives in haystack-like hovel; leads a solitary life; cannot read; possesses but a slight degree of intelligence.

"Diet—Breakfast, black bread, oil, water; dinner, black bread, oil, water; supper, black bread, oil, water. This meager and monotonous diet is varied at frequent intervals by a very small piece of bacon, salt pork or macaroni, an onion or a little funnochio; on great fete days by a little wine.

"Earnings at seven cents a day, \$25.55.

"Cost of Living for the Year—Bread, \$14.60; oil, \$5.47; other food supplies, \$1.82; clothing, \$3.66.

"Expenditures, \$25.55.

"Earnings, \$25.55.

An Old Man's Record.

A methodical man died in Berlin recently at the age of 73 years. When 16 years old he began keeping a record, which he continued for 52 years, which is the best commentary we have seen on the life of a mere worldling. His book shows that in 52 years this "natural man" had smoked 638,715 cigars, of which he had received 43,692 as presents, while for the remaining 585,021 he had paid about \$10,433. In 52 years, according to his book-keeping, he had drank 28,780 glasses of beer and 36,086 glasses of

spirits, for all of which he spent \$5340. The diary closes with these words: "I have tried all things, I have seen many, I have accomplished nothing."

A Lake in the Clouds.

A triumph in engineering is reported from the mountains of Peru, where a twin-screw steamer of 540 tons, 170 feet long and 30 feet wide, has been successfully launched on Lake Titicaca, the highest navigable waters in the world, more than 13,000 feet above the sea.

The steamer, which belongs to the Peruvian Government, and is to be used for freight and passenger traffic, was built on the Clyde, then taken apart in more than a thousand pieces and shipped to Molendo by sea. It was then carried to Puno by railway and transported over the mountains on the backs of llamas and mules, and put together by a Scotch engineer.

Diamonds in the United States.

Diamonds occur in the United States in two regions. One extends along the southern base of the Alleghany mountains from Virginia to Georgia; the other on the western side of the Sierra Nevada and Cascade ranges in northern California and southern Oregon. The mineralogical conditions of these two remote regions are very similar, and the discoveries made in them are much alike. The formations in the diamond-bearing localities of the United States are very much like those of Brazil and India, and very unlike those of South Africa, where the great diamond fields of the world lie.

Where the Money Went.

When the Midway Plaisance people were leaving Chicago, bankers were kept busy for quite a while in changing \$1,000,000 or more, which they carried away as the result of a summer's industry, into the coin of other realms. A donkey boy from Cairo street unrolled a tattered cloth containing \$700 in silver, for which he wished French francs, while a camel driver had a clear \$1000. An Arab, a Turk, a Nubian soldier and a Persian dancer each had a little fortune of \$1000 in silver.

A PROCESS devised for renovating old belting is claimed to strengthen the fiber of the leather to a remarkable degree. The belting is passed through a tank containing a solution of beeswax, borax, glue, starch and molasses in equal quantities, and the compound is then squeezed into the fiber by press rollers. The leather is immediately dried by being passed between two steam-heated copper cylinders, and the renovation is complete.

A CURIOUS FEATURE about Japanese journalism is that every important paper is said to have a "prison editor." Japanese journalists are so constantly being fined and sent to prison that the sole occupation of the individual is to go to jail when called upon.

MAKING many copies of documents inflicts upon the typewriter operator a peculiar sort of nervous exhaustion. In well-conducted offices these copies are now given in rotation, alternating with other work.

THE function of the negro's black skin is now supposed to be the conversion of the sun's light into heat. The heat thus generated remains in the skin, never penetrating to the deeper and more vital tissues.

AUTOMATIC watches, which show the time by changes in figures each minute instead of by the ordinary hands and Roman numerals, are becoming quite fashionable.

THERE are many horses that have never been seen to lie down in their lives. Their rest is not complete, however, and the joints and sinews are liable to stiffen early.

Diamond Mining.

The De Beers and the Kimberley mines are probably the two biggest holes which greedy man has ever dug into the earth, the area of the former at the surface being 13 acres, with a depth of 450 feet, the area and depth of the latter being even greater. These mines are no longer worked from the surface, but from shafts sunk at some distance from the original holes, and penetrating to the blue ground by transverse drivings at depths varying from 500 to 1200 feet. The blue ground when extracted is carried in small iron trucks to the "floors."

These are made by removing the buns and grass from a fairly level piece of ground; the land is then rolled and made as hard and as smooth as possible. These "floors" are about 600 acres in extent. They are covered to the depth of about a foot with the blue ground, which for a time remains on them without much manipulation.

The heat of the sun and moisture soon have a wonderful effect upon it. Large pieces which were as hard as ordinary sandstone when taken from the mine soon commence to crumble. At this stage of the work the winning of the diamonds assumes more the nature of farming than of mining. The ground is continually barrowed to assist pulverization by exposing the larger pieces to the action of the sun and rain.

The blue ground from Kimberley mine becomes quite well pulverized in three months, while that from De Beers requires double that time. The longer the ground remains exposed the better it is for washing. The process of exposure being completed, the blue ground is then carried to very large, elaborate and costly washing machines, in which, by means of the action of running water, the diamonds are separated from the ordinary earth.

It may be mentioned that in this process too loads of blue ground are concentrated into one load of diamondiferous stuff. Another machine, the "pulser," then separates this latter stuff, which appears to be a mass of blue and dark pebbles of all shapes, into four different sizes, which then pass on to the sorters.

The assorting is done on tables, first while wet by white men, and then dry by natives. The sorters work with a kind of trowel, and their accuracy in detecting and separating the diamond from the eight different kinds of mineral formations which reach them is almost unerring.

Literary Note.

Notable articles in the May *Overland* are: "Egypt To-day," by Hon. Jeremiah Lynch, author of "Egyptian Sketches"; "The Palmistry of China and Japan," by Professor Stewart Cullen, of the University of Pennsylvania, the first article on that subject in the English language; "The Collie in Mendocino," a beautifully illustrated paper; "The Nicaragua Canal," by Lieutenant Winn, U. S. A. (military advantages), and Captain W. L. Merry, Consul-General of Nicaragua (political aspect); "King Solomon's Mines," by Rounsevelle Wildman, the editor, a Malayan sketch; "The Chinese Six Companies," by an educated Chinaman, intended to correct much popular misunderstanding; and "More Rambles on the Midway," a continuation of the elaborately illustrated Midwinter Fair articles.

If advanced electricians are not altogether too sanguine, we may soon be able to carry on telegraphic communication without wires. Mr. Preece, the eminent English electrician, in a recent paper, gave it as his opinion that it would be quite easy to speak between France and England across the straits of Dover without any metallic connection.

PETROLEUM has been successfully used to prevent the incrustation of boilers and remove the scales already formed.

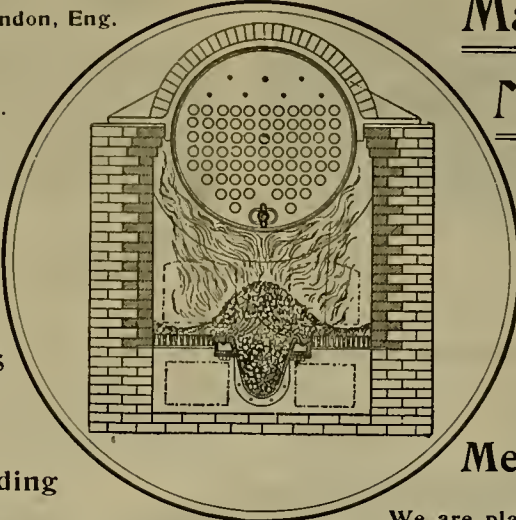

Fraser & Chalmers, Mining and Power Machinery.

Metallurgical Plant.

We now have sole control and manufacture of the

Jones Underfeed Mechanical Stoker.

We are placing these Stokers like "Hot Cakes," 23 to one Company. Send for Testimonials of their remarkable results in saving coal and making steam.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Oupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages, with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner..... \$550, f. o. b.
 " " " Improved Belt Frue Vanner 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner 800, f. o. b.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

For any information, or for pamphlets, or for circulars or testimonials, call on or address
H. J. SUMMERHAYES, Successor to Adams & Carter, Agent for the FRUE ORE CONCENTRATOR.
 No. 132 Market Street. — San Francisco, Cal.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable. Price \$575 f. o. b. Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allotted to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft, self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

GEO. E. WOODBURY, Manufacturer, 213 to 219 First Street, San Francisco, Cal.

[COPY]
 Eureka Tellurium Gold Mining Company, Redding, Cal., July 21, 1893.—Mr. Geo. E. Woodbury, 213 First St., San Francisco, Cal.—Dear Sir: We take pleasure in stating to you that the two Ore Concentrators purchased from you last April are giving perfect satisfaction. They are simple, durable and effective, and we hereby conscientiously recommend the "Woodbury" pattern to all intending purchasers of Ore Concentrators. Yours truly,
 [Signed] EUREKA TELLURIUM GOLD MINING CO., by GEO. O. JONES, Secretary.

PATENTED Aug. 19, 1890.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

The arrangement made by S. W. Bright, who has bonded the Bellwether mine at Jackson to a Montana capitalist, is to the effect that ten stamps are to be erected within ninety days, and sixty more within fifteen months.

Calaveras.

New Incorporation.—The Gwin Mine Development Company has filed a copy of its articles of incorporation in the Clerk's office in Calaveras county. The objects of the company as set forth in the articles are to purchase, lease, develop hold and operate mining ground. Its principal place of business is in San Francisco and its capital stock is \$1,000,000, of which \$25,000 is subscribed. The directors are David McClure, Jr., of Oakland, Frederick F. Thomas of San Francisco, Edward C. Voorhees of Sutter Creek, Mortimer W. Belshaw and Charles P. Eells of San Francisco.

The Calaveras Prospect says: There is an increased activity in mining circles all over the county, and old mines are being reopened and new prospects developed every day. The county is full of prospectors, and new faces are to be seen in every mining camp, giving life and animation to old places.

Work has been resumed on the Esmeralda mine, in Calaveras county, owned by Hon. John F. Davis of Jackson. Only a small force of men is at present engaged, but the mine is being put in shape for more extended operations.

A group of four mines along the river from Robinson's Ferry, in Calaveras county, and owned by Mr. Viertong, are reported to have been sold for \$109,000.

Madera.

GAUB GULCH.—*Mercury:* There is somewhat of a boom in mining matters in Grub Gulch and Coarse Gold. The mines in both these places are looking fine and a big force of men are employed there. D. M. Tomblin's mine at Grub Gulch is looking well and considerable rich ore is being taken out. Everything about that burg is bustling on account of the mining business there. Lindey & Lee's mine at Coarse Gold is exceeding the highest expectations of the owners. A large quantity of rich ore is being taken out. A force of men will be steadily employed getting out ore. It is not intended to begin milling operations until such a body of ore is taken out that it will be sufficient for a long run. Philip E. Chapin, a capitalist of Washington, has purchased a one-third interest in the mine.

Nevada.

BIO STRIKE.—*Union:* A rich strike of gravel has been made in the Odin drift gravel mine. Gravel has been found that will pay as high as \$40 to the carload. The strike was made in the north drift, and at a depth from the surface vertically of about 175 feet. This gravel deposit is known to be fully 200 feet in length; how wide it is has not been determined yet.

THE ECLASTIC MINE.—*Telegraph:* The ten-stamp mill of the Eclastic mine has started up. The shaft is down 400 feet. The drifts at the 300 level have been run 156 feet north and 100 feet south. The ledge varies in width from 13 inches to 25 and 26 inches, and there is scarcely a piece of it but what free gold can be plainly seen. The rock is considered to be more than the average milling ore. There is now about 150 tons of the ore on the surface and there is a large amount of it opened up in the mine.

Placer.

Colfax Sentinel: At the Polar Star mine at Dutch Flat, last week, a very good prospect was found in the prospect drift that is being run from the old hydraulic pit. If a sufficient quantity of the same kind of gravel can be found, it will pay well to drift.

There is some talk of the Liberty Hill Company raising their dam in Bear River and renewing hydraulic mining at Liberty Hill. The raising of this dam would allow all mines above it to work and would include the Polar Star.

Messrs. Wilkie, Waite, Peters and Feeley have leased a piece of ground from Mr. Spaulding, and will proceed to drift and ground-slice it. The company will be known as the B. P. Co. (Bright Prospects Company.) The men comprising the company are all experienced miners and are "up to date" in mining matters.

Jerry Goodwin of Yon Bet has almost completed his arrangements for working the tailings at Red Dog by the elevator process. In the incline, considerable water has been encountered, and it will be necessary to put in a pump.

San Bernardino.

RICH ORE.—*Epitaph:* Four Redlands men, returning from the desert, brought a large quantity of ore from a prospect they discovered 18 miles northwest of Panamint. Several assays average over \$1000; a few over \$2500 a ton. Expert miners declare it is the richest ore ever exposed in southern California.

NEVADA.

Washoe District.

Following are copies of the official letters of Comstock mine superintendents for the week:

CON. CAL. & VIRGINIA.—On the 1650 level the crosscut running east from the end of the crosscut run east from the drift run north from the end of east crosscut No. 1 from the north drift from the winze—down 52 feet—has been extended 10 feet; total length, 20 feet, passing through porphyry and streaks of quartz of low assay value.

In prospecting the ore body which was en-

countered 120 feet south from the winze, when last week we cut through six feet of good ore, we have this week entered the same body at a lower depth, and have advanced a south drift therein 54 feet in solid, compact ore, and have extracted 52 carloads—about 50 tons—the average assay value of which, per car sample assays, is \$79.20 per ton. This drift is 14 feet below the sill floor of the 1650 level. The workings of last week were inadvertently reported as being 20 feet below that sill floor, whereas we have found from subsequent measurements that they should have been reported as being on the line of the sill floor.

On the 1000 level—the Knle drift—the drift running south from the crosscut run east from the drift run south from the raise (50 feet up) 353 feet south from the shaft station has been extended 20 feet; total length 36 feet, in vein matter. From the end of the south drift from this raise (50 feet up) a west crosscut has been advanced 25 feet in porphyry and quartz of low assay value. West crosscut No. 3, 590 feet from the shaft station, has been extended 25 feet; total length 55 feet, in porphyry and quartz. At a point 555 feet south from the shaft station, are cutting out on the east side of the main drift an opening from which an upraise will be carried up.

OPHIE—1465 level.—The drift run south from the crosscut run west from the main north drift, at a point 219 feet in from the mouth of the crosscut, has been extended during the week 11 feet; total length 55 feet, continuing in porphyry showing lines of quartz.

As joint work with the Mexican Company, repairs have been made in the main shaft at and near the 700-level station.

Central Tunnel.—Have been engaged during the week in repairing the old Mexican shaft station, with which the drift connected, and in catching up and retimbering the broken ground around the shaft for a distance of 37 feet.

MEXICAN—1465 level.—The upraise started near the mouth of the crosscut run west from the drift run south from the top of the upraise, which was carried up 45 feet above the sill floor of this level at a point 40 feet west from the main north drift and 100 feet north from the south line of the mine, has been carried up during the week 7 feet; total height, 81 feet; continuing in a very hard porphyry formation.

As joint work with the Ophir Company, repairs have been made during the week in the Ophir shaft at and near the 700-level station.

ALTA.—The intermediate winze is down 12 feet and the bottom shows 28 inches of high-grade ore, the assay value running from \$12 to \$250 per ton, 80 per cent of which is gold. Directly over this point and above the 725 level we are raising a header in ground that looks very encouraging because of the continued improvement as we advance. The north raise has been advanced 17 feet during the week; total length 117 feet.

HALE & NORCROSS—900 level.—Advanced the southwest drift 12 feet; total length, 204 feet; face in porphyry.

1100 level.—Advanced the main south drift 10 feet; total length, 203 feet; face in porphyry. Have started a west crosscut from the end of this drift. We are retimbering a part of the station on this level. Commenced yesterday shipping ore to the Brunswick mill.

UNION MINE—900 level.—The Union Con. and Sierra Nevada joint west crosscut started near the north line of the Union mine, from the joint north drift which was run from the joint west drift, at a point 1520 feet west of shaft, has been extended during the week 20 feet; total length, 335 feet; face in hard porphyry.

WEST CON. VA. & CAL.—During the past week the west crosscut on the 1100 level, run from a point 320 feet north of the shaft station, has been extended 28 feet, and is now in a total distance of 733 feet. The face in hard quartzite. The flow of water is unchanged since the last report.

KANTUCK.—From the east crosscut on the 1035 level we have started a south drift in ore of fair quality.

1200 level.—The south drift from the Yellow Jacket incline is in a total distance of 60 feet, the face in low-grade gold ore.

BEST & BELCHAM.—On the 800 level west crosscut No. 2, which has been run in the north drift at a point 180 feet from our south boundary, has been cleaned and repaired for a distance of 200 feet.

GONLE & CURRY.—On the 200 level west crosscut No. 5, started in the northwest drift, 432 feet from the main west drift, has been extended 25 feet; total length, 1053 feet; face in soft porphyry.

OCCIDENTAL.—From the west ledge above the 400 level we continue to extract about 8 tons of ore per week showing an average value of \$46 per ton.

ANDES—420 level.—The upraise started in the west crosscut No. 1 from the main north lateral drift was carried up 13 feet during the week, continuing in quartz.

SERRA NAVADA.—The south lateral drift from the intermediate tunnel has been advanced 26 feet; total length, 659 feet; face in hard porphyry. The joint west crosscut near the north line of the Union mine from the north drift 1520 feet west of the shaft, 900 level, has been advanced 20 feet; total length, 35 feet; face in hard porphyry.

UNION SHAFT.—Have started a joint west crosscut near the north line of the Union mine from the north drift, 1520 feet west of the shaft on the 900 level, and advanced same 20 feet; total length, 35 feet; face in hard porphyry.

CHOLLAR.—The north drift, 100 level, has been extended during the week 31 feet; total length, 170 feet; face in soft vein material composed of porphyry and streaks of quartz.

The west crosscut on this level, 300 feet south of the north line, was extended 34 feet; total

length, 166 feet; face in porphyry with streaks of low grade quartz through it.

POTOSI.—The south drift on the 450 level has been advanced 21 feet; total length, 369 feet; face porphyry, the ore streak having passed to the west of the drift. The south drift, 50 feet above the 450 level, is out 104 feet, having been advanced 22 feet; face in clay and soft porphyry.

WAAN COMBINATION SHAFT.—The west drift from the station, 820 level Ward shaft, is out 760 feet from the shaft. Progress has been slower than usual, due to soft ground with a considerable amount of water running through it, necessitating careful timbering.

BULLION.—The west drift from the station, 820 level, Ward shaft, is out 760 feet from the shaft. Progress has been slower than usual, due to soft ground with a considerable amount of water running through it, necessitating careful timbering.

SAVAGE.—On the 1050 level the north drift from the station was advanced 24 feet, making its total length 82 feet. The south drift was advanced 13 feet, making the total length 190 feet from the shaft; face in quartz and porphyry. In the west crosscut from the south-east drift, started at a point 225 feet from the shaft, they have stopped some pay ore. The upraise from the north drift, started from the east drift at a point 85 feet south of the shaft is advanced 18 feet; top in quartz giving low assays. On the 1100 level the north drift from the shaft was advanced 16 feet, making its total length 178 feet; face in favorable looking quartz and porphyry.

On the 12th floor they are extracting some pay ore.

During the week they hoisted 34 cars of ore, car samples averaging \$36.21.

BELOAR.—On the 850 level the north drift has been cleaned out and retimbered a distance of 25 feet, making its total length 390 feet from the shaft. During the week 25 tons of fair-grade ore were extracted and hoisted to the surface.

CROWN POINT.—The south drift from the top of the 700-level raise on the 600 level is now out 81 feet. The face is in a mixture of porphyry and quartz. The south drift on the 7th floor of the 700 level raise is now out 70 feet. The face is in porphyry and low-grade quartz. The south drift from the station on the 500 level is out 62 feet. The formation in the face is in a mixture of porphyry, clay and low-grade quartz.

SAG, BALONEZ.—The west crosscut from the end of the north drift on the 1150 level is now out 20 feet, having been extended nine feet since last report. The face is in a mixture of porphyry, clay and low-grade quartz.

We continue to save a few tons of fair-grade ore per week from the south raise on the 1150 level.

IOWA.—Clearing out caved ground at the mouth of the Iowa tunnel. Expect to have this tunnel cleared up and commence work in the west crosscut in a few days.

REWORKINGS.—*Enterprise:* A number of unemployed miners are working over the old waste-rock dumps at the various hoisting works in search of ore, and some of them manage to make fair wages.

A tunnel is being run into the Cumberland ground between the Iowa and West Con. Va. & Cal., and as it is about as far west as the Rowe find there is a favorable prospect that some of the stringers cut will make into a paying body, as the ore in that vicinity is exclusively gold-bearing.

There are numerous narrow surface veins of quartz on Cedar Hill that unemployed men would be willing to work on royalty if leave could be obtained from the mining companies owning the ground. These veins are too narrow and uncertain to pay a company to work, but practical miners could make a living in going out the ore.

The discovery of a four-inch vein of quartz, showing an average value of \$20 in gold per ton, has recently been made north of Jumbo district, in the vicinity of the location formerly owned by Lawyer Thomas.

A search will be made this year for the vein from which the float gold quartz drifted found near the head of Little Valley, where a hydraulic claim was worked in the early sixties.

Soda Springs District.

THE SONA SPRING MINES.—So far eleven gold-bearing mines have been discovered in Soda Springs district, Esmeralda county, on the line of the Carson and Colorado Railroad, fifty miles south of Hawthorne. One ledge five feet wide has been uncovered that shows plenty of \$200 rock. Another, four feet wide, shows up a big body of \$40 ore; and still another five-foot ledge that assays \$70 per ton. What is termed as the "waste rock" assays \$20 per ton. The district as a whole will average anywhere from \$20 to \$70 per ton. The district is attracting much attention, and the Reno Gazette says the camp is likely to contain 3000 to 4000 people before fall.

ARIZONA.

MINE BONDER.—*Journal-Miner:* A bond has been executed to C. W. Culver from Messrs. Askew, Herndon, Kingley, Thornton and Crane for the Moscow mine, the consideration being \$150,000. The mine affected by this transaction lies in the Agua Fria district, about four miles from the Bowers ranch, and is the property over which there was considerable excitement about a year ago on account of its richness. It has been in litigation until recently. Mr. Culver will leave in a few days for the East on business connected with its sale.

MOJAVE MINER: As the price of silver is dropping down toward the 50-cent notch, the Prince Albert mine, White Hills, is sending out the richest ore ever taken from that camp. The last shipment from the mine was valued at

something like 3000 ounces in silver and six ounces in gold per ton.

BRITISH COLUMBIA.

GONA BACK TO CARIBOO.—*Spokane Review:* The old Cariboo country, which in former years turned out \$60,000,000 in gold, may have a new lease of prosperity this summer. A company is now working ten miles east of Barkerville, on an enterprise which its promoters believe will result in bringing more gold to the surface than has yet come out of the district. The plan is to sink a shaft to the bottom of the old channel of Slough creek, which drains half a dozen smaller streams, each of which has in the past yielded from \$1,000,000 to \$2,500,000 in gold.

W. F. Sargent of Tacoma, secretary of the company, was in town lately and gave a description of the company's work. "We secured a Government lease two years ago," he said. "It covers a section of the Slough valley, one-half mile wide and three miles long. Then we began drilling holes at intervals of 100 feet across the valley. Finally we found the deepest point in the old channel, after passing through 40 feet of gravel, 160 feet of clay and 45 feet more of gravel to bedrock. Next we ran a drainage tunnel 2150 feet long to the top of the clay bed at the point where we are to sink the shaft. The contract for sinking the shaft has been let and we hope to have it finished so we can begin work at bedrock in July or August.

"If there is anything in it there are millions, and we are confident that we will get plenty of gold. This is the old channel through which the water ran for thousands of years before taking its present course. If the upper bars can now pay their millions year after year, what must the bedrock be like?"

COLORADO.

THE CRIPPLE CREEK SITUATION.—The Cripple Creek Crusher gives the following relative to the strike at that place: There is no gainsaying the fact that up to the present time the miners are ahead in their contest with the mine-owners. There are now 28 mines working on the old 8-hour schedule and employing in the neighborhood of 600 men, while two, with the sanction of the union, are working nine hours for \$3.25.

The total number of mines now idle by reason of the labor trouble is seven, and with full crews they would not, if all started up, employ over 300 men.

The owners of the idle mines may as well look the facts in the face; the miners and a majority of the mine-owners of the camp are against them, and unless they have a trump card of the highest value yet to play they may as well concede themselves beaten and take their medicine with as good a grace as possible.

PHARMACIST ORA IN SIGHT.—*Record:* Within the last three months the Pharmacist mine at Cripple Creek has been thoroughly inspected by two prominent experts, who figured on the ore in sight, and the lowest calculation put the figures at \$120,000. It is understood that the property is now being examined by an English expert for an English syndicate, and should negotiations fall through on the deal now pending, in two weeks the mine will be started up to earn dividends.

MINING FLOAT.—*Esquire:* The Tillie Butzel shipped \$3500 worth of ore in March, the work of about a dozen men. The ore in the Queen Bees is improving with each foot driven, the ore brought out last Saturday showing well in copper pyrite. Clear Creek County.—In Empire district, the Badger Boy has shipped eight tons of quartz, which returned \$35 per ton, while the Gold Dirt has 15 tons ready for shipment. At Yankee Hill a rich strike has been made in the Jennie Moore. The Clear Creek Placer Co. has commenced operations on its property, near Idaho Springs, Chaffee County.—The old gold camps of the sixties, near Granite, are showing signs of renewed life, and will be the scene of active operations this summer. El Paso County.—The Portland Company has bought the Queen of the Hills, Vanadium, Hidden Treasure and Baby Ruth, which were in conflict with its property, thus removing all possibility of litigation from that source. The price paid was \$100,000. At the McCloud mill an intelligent test of the cyanide process is now being made. The Appie Ellen has struck it rich—three feet of ore running from \$40 to \$300 per ton. Fifty tons of smelting ore are now ready for shipment. The Gould Company has been in great luck during the past week—a big strike in the Nil Desperandum and the adverse suit of the Pueblo Consolidated Mining Company against the Rhinoceros decided in its favor. The Something Good, of the Aola Company, shows ore covered with eylvanite. The Elkton, Raven, Moose and other old producers are keeping up their records. Gunnison County.—A custom stamp mill is about to be erected on the Cholla to treat Goose Creek ores. The Iron Cap, of this district, has a car of ore ready for shipment, which shows well in free gold. Sale of good prospects are now being made in this camp. A syndicate of Boston capitalists has taken hold of the Taylor River placers, and will spend \$100,000 this season in placing water upon them sufficient for hydraulic mining on a large scale. Lake County.—The largest cyanide mill in the State will be erected at Leadville to treat the low and medium-grade ores of the gold belt. La Plata County.—A 25-ton concentrating mill is being built at La Plata City. Development work is being pushed on some of the claims in the La Plata mountains as fast as men and money can drive. Mineral County.—The United Mines Co., at Creede, is about to enter the list of shippers. The Amethyst, New York Chance, Last Chance, Batchelor and Ridge are shipping from 20 to 25 cars of ore per day. If the price of silver advances, this will be increased materially. Keep your eyes on the Bear Creek

gold district. Ouray County—The Grand View was sold last week for \$75,000. The Osborne & Loder smelter, below Ouray, will blow in next month. It is promised that the Anstin process smelter, at Ridgway, will be ready for business September 1st. If this proves true, look out for Bright Diamond and Iron Clad stocks. Park County—Development in the Balfour district is proving the general formation to be the same as the famous Cripple Creek camp, and many practical mining men believe it to be in the same mineral-bearing zone. There is no doubt but that a number of shippers of good-grade ore will be developed there this season. Pitkin County—The Tam O'Shanter, Montezuma and Express, at Ashcroft, have large amounts of ore, mined during the winter, ready for shipment.

IDAHO.

PROPERTY BONDED.—Says the De Lamar, Idaho, *Nugget*: The Dr. Stephen H. Emmons syndicate has recently bonded the Rajah and Mammon mines, on Florida Mountain, from Messrs. Crosson, Smith and McLain, and the Banner and several other claims from the respective owners. Development work will begin as soon as practicable on these properties.

PROPERTIES AROUND HAILEY.—*Mining Area*: The Star mine has encountered a fine body of high-grade ore and is putting on more men at once. The Red Elephant mine is working thirty-three men, and is now running both day and night shift. The Red Cloud people are working forty men and have a fine body of ore. The Texas Star Gold Mining Company is employing twenty-five men. Their mill is turning out a fine gold brick each week, and shipping a carload of concentrates a week. The Fanny Warring mill is about in readiness to start up. They have plenty of ore to crush.

The Tyrannus has a fine showing. The Stormy Galore is making shipment of 400-ounce ore. The Carrie Leonard leasers have a large quantity of ore out. The Flagstaff is tapping its ore at a greater depth. The Idaho Democrat people have uncovered another rich bunch of ore. The Idaho Republican owners are getting in readiness to resume. The Washington mine is working a small force. The Hidden Treasure claim has two men at work. The Narrow Gauge mine on Deer creek is looking fine. Elk-horn gulch leasers are all regular shippers. The Philadelphia Company is doing no work, merely leasing. All the machinery of the North Star property has been pulled out, for what reason no one knows. Assessment work is being done throughout the entire belt. The Hard Times mine is working six men. The Queen of the Hills Company is working twenty men, and has bonded two adjoining claims. This is a great property, and the systematic way the new company is going to work will be a big lift to this community.

Nothing is being done at the Minnie Moore, Relief or Michigan claims, owing to the low price of silver. The O. K. mine has a good showing of rich ore. Mr. Lippman of Salt Lake has arrived and put a force of men at work on the Point Lookout mine. The Hope and Cressus mines have been sold to a Colorado syndicate. These are two very promising claims, carrying \$6 to \$20 in gold. For a number of years they have been prospected thoroughly and opened up for sale. The Independent group of mines is still idle. The Mayflower has a force of men at work; also the Bullion and Jay Gould; they all have a good showing. Twelve to fifteen cars of ore leave here weekly, and from four to six cars of bullion. The sampler is working a complement of men.

MONTANA.

THE COLORADO SMELTER FIRE.—Butte *Inter-Mountain*: Henry Wolcott of Denver, the secretary and treasurer of the Colorado Smelting and Mining Company, says that the Colorado smelter, which was consumed by fire, will be rebuilt at once. The amount of the damage is estimated at about \$100,000. It is said there is no insurance on the works.

NEW MEXICO.

CENTRAL DISTRICT.—*Enterprise*: The Texas mine shows no diminution of the ore bodies. Another shipment of rich ore is nearly ready to send to the smelters. The returns from the last shipment of two lots of ore and one lot of concentrates gave returns as follows: Ore, lot No. 1, 388 ounces silver and one ounce gold per ton. Ore, lot No. 2, 274 ounces silver and one ounce gold per ton. Concentrates, 407 1/2 ounces silver and 7.4 ounces gold per ton. The concentrates were from the refuse or low-grade ore, of which there are thousands of tons lying on the dump, from which the higher grade ore was assorted and shipped.

The Owens & Porter mill has been shipping bullion and concentrates.

WASHINGTON.

OREVILLE, Okanogan County, Wash.—Prospects and times look promising for the Okanogan country. Depression in the price of silver has caused attention to be given to the old placer camps and the gold belt of north-eastern Okanogan county. Numbers of miners and prospectors are daily arriving, and at present there are more than 100 men washing and sluicing on the Similkameen river from one to ten miles above the town of Oroville. Extensive development is being done upon the several properties extending from Loomiston to the British line. A syndicate has bonded the Black Bear and War Eagle on Palmer mountain, and has let a contract to sink the shaft of Black Bear a depth of 300 feet.

OREGON.

JOSEPHINE COUNTY.—*Courier*: Woolfolk & Son are running an arrastra by horse power on their ledge in Dry Diggings, and the ore is fairly yellow with gold. The formation is a mixture of decomposed quartz and granite and there is big pay in the crushings. The owners are pre-

paring to run their arrastras with water power. J. C. and A. E. Root are developing the Black Bess ledge on Coyote creek in company with L. G. Geary. The vein of gold-bearing quartz has been traced under the mountain, and it is found cropping out unmistakably on the Wolf creek side.

The Ennis-Cameron placers on Galice creek are being operated night and day and there is an abundance of water for four months yet. The wages paid miners on this property range from \$2.50 to \$3.50 per day.

The Garrett ledge on Bamhoo gulch near Williams creek is paying wonderfully, \$20 to the pan being taken out by a crude mortar process. This is not a pocket, but a very rich ledge which bears every indication of permanency.

GEANT COUNTY.—The placer mines of northern Grant have started up business, and many hydraulics are spouting with every assurance of a long and continued water supply. The miners say that if gold straight is to be the rule, it is well enough to dig and get action on it.

There are now 60 men at work on the Hampton mining ditch in the Grave Creek district, and it is thought the construction will be finished in May. The company has 760 acres of rich placer ground which is covered by the ditch, and will utilize the whole flow of Grave creek in its operations.

SOUTH DAKOTA.

DEEPEST SHAFT IN THE HILLS.—Deadwood *Pioneer*: The contract has been let to sink the Star shaft of the Homestake mine 100 feet deeper. The shaft is now down 800 feet. The contract was awarded to the contractor who put the shaft down 200 feet below the 600-foot level. In reality the shaft will be, when this last shaft shall have been sunk, 930 feet deep, as there will be a 30-foot sump driven below the last station.

Coast Industrial Notes.

—The Western Sugar Refinery has reduced prices of all grades 1/4c.

—Santa Fe boiler-makers who have been on a strike in San Bernardino have returned to work.

—The Nelson shingle mill at Anacortes, Wash., shipped 5,850,000 shingles East during March.

—About 200 Canadian Pacific employees have been laid off in the machine shops of the railroad at Vancouver, B. C.

The Placerville Electric Light Company has secured a 1000-light plant from the Pacific Electrical Storage Company of this city.

—It is thought that the interest on the O. R. and N. Co.'s mortgage 5's and 6's will be defaulted for December, which would occasion foreclosure proceedings.

—The reports of rainfall for the present season credit Auburn with 30.72 inches of rain and Newcastle with but 14.56 inches, though the two places are only four miles apart.

—Some weeks ago A. Lusk & Co., canners, were forced into insolvency. The assets were appraised at \$204,000, but the returns show that only \$784 was realized from their sale.

—Four cents is the ruling price for sheep-shearing in Grant county, Or., this season. It is "not wages," but has to be put up with, along with the reductions in other occupations.

—Out of 187 plans submitted for Washington's new State Capitol building the Commission has selected that of Ernest Flagg of New York. The building will cost \$1,000,000.

—There are now 15 oil wells flowing near Los Angeles. The yield is steadily increasing, as new wells are being bored all the time. The oil finds a ready market at \$1.50 to \$2 a barrel.

—The experiment of bringing crude oil from Peru is a success. The Bawnmore, chartered by J. W. Grace & Co., brings 840,000 gallons, which finds ready purchase by the San Francisco gas companies.

—The unwisdom of forcing sale of city property at present is illustrated in the case of the property of the State Investment Co. A year ago it was valued at \$155,000. Last week it was sold at forced sale for \$79,670.

—The mills of Vancouver are exporting a good deal of lumber to Australia and Chili. The mills sell at \$7.50 per M. by the shipload, ordinary lumber, and the Tacoma *Ledger* says they take things easy all the while.

—The Gray's Harbor Commercial Company is filling an order for 50,000 feet of fir and spruce finish to go into a cruiser which the Cramps' shipyard at Chester, Pa., is getting ready. This is the first order from them.

—The Inyo *Register* says: "It is to be hoped in the name of humanity that the newspapers on the other side will stop publishing the absolutely untrue story that men can obtain work on the 'Mt. Whitney canal' at big wages, and cash twice a

month. So far they can get no cash at all—there has never yet been a pay-day. There is no certainty as to the time when there will be."

—Trainloads of sheep and cattle are being moved from the San Joaquin and Salinas valleys to the stock ranges in Utah and Nevada, where the pasturage is uncommonly good this season. An emergency rate of from \$25 to \$60 a car has been made.

—The Metropolitan Street Car Company are putting in a Thompson-Corliss tandem compound engine of 700-horse power in their First avenue power-house, and will add ten new cars to their plant. They propose opening a branch from Ninth avenue to the ocean.

—The Truckee *Republican* says the mill-saws of the Truckee Lumber Company make welcome music in the air, announcing the opening of the lumber season. Both sides of the mill are running, and 70,000 feet per day are being turned out. Nearly 2,000,000 feet of logs are in the pond, and the Donner and Tahoe railroad will be ready to rush in 75,000 feet per day additional in a couple of weeks. The company intends to saw 10,000,000 feet of lumber this year, which will be the largest cut made in twenty years.

—Talking of the available rights of the South Yuba Water Co. and its value as a motor, Dr. Chas. Van Norden, the Auburn director of the company, says: "We could have 3000-horse power in Sacramento in a very short time. We have water enough at Newcastle for that amount now, and could get more very soon, as soon as it would be needed. We could furnish over 50,000-horse power; that is, by taking the water from our 42 canals, which aggregate 380 miles. Besides this, we are continually improving and adding others to our system. We have over \$1,500,000 of actual money in this work, and counting what we inherited, it would bring up the actual cost of the plant to over \$3,000,000."

—The following local incorporations disbursed dividends during April:

Market Reports.

The Markets.

SAN FRANCISCO, May 3, 1894. Silver declined and advanced during the week, going down to 63½ and appreciating to 64½. Those whose position lends warrant to their opinions think it will be more buoyant as the summer wears on. The drop in the early part of the week was occasioned by an authentic denial of the rumor that the India mints would be reopened. The international bimetallic conference, now in session in London, will, it is believed, by the result of its deliberations, give tone to the market.

The money market has been of inadequate supply during the week, greatly owing to the unusual plethora of the Bank of England's resources. During the week that institution had, as reserve, \$23,250,000, the highest amount on record. As noted elsewhere, local corporations disbursed during April dividends aggregating \$519,166. The local bank clearings in April were \$56,629,775; they were \$61,520,063 in April, 1893; making the totals so far this year \$213,264,599, against \$254,849,807 for the first four months of 1893.

The local bullion, money and exchange quotations current are as follows:

Mining Share Market.

SAN FRANCISCO, May 3, 1894.

The mining share market developed unusual strength during the week, and those who prophesied a setback in comparison to last week's prices found their mistake to be a costly one where opinions were backed by coin. At the delinquent sale of the Con. Cal. & Virginia but 6100 shares of the 216,000 were offered, and at the Andes delinquent sale only 820 of the 100,000 shares were offered. Con. Cal. & Virginia sold up to \$6, and the other

stocks shared to the advance. More men have been put at work in the Con. Cal. & Virginia, Ophir, Belcher and other mines, and during the week but two of the Comstock superintendents were absent from their posts.

This morning Con. Cal. & Virginia ran up to \$6 62½ on sales between boards, and prices were up all along the line. It looks as though there was more in this than "the regular spring advance," the favorable reports from the mines and the piles of idle money in the banks favoring the present upward movement.

Northwestern Incorporations.

—The following are recent Northwestern incorporations:

The Spectacle Lake Gold Mining & Milling Co., at Loomis, Wash. Capital stock, \$1,000,000, with shares at \$1 each. Incorporators: G. W. Adrian, W. M. Adrian, of Loomis, Wash., Wm. Foule of St. Paul, Minn.

The Canadian Northwest Mining Co., at Helena, Mont. Registered in British Columbia. Capital stock, \$2,000,000, with shares at \$5 each.

The Gold Cable Mining & Milling Co., at Tacoma, Wash. Capital stock, \$1,200,000. Incorporators: C. W. Moorill, J. Q. Mason, E. L. Shaffer, C. M. Johnson, R. A. Crothers, L. U. Loomis, T. H. Donavon, G. J. Turrell, F. M. Wade, J. L. McMurray, R. Metcalf.

The Chassel Gold Mining Co., at Basin, Mont. Capital stock, \$500,000, with shares at \$1 each. Incorporators: Geo. Pease, J. H. Rule, Louis Sponheim, O. A. Lanning, of Basin, Geo. Robertson of Butte, Mont.

The Eureka Mining & Real Estate Co. of Leavenworth, Wash. Capital stock, \$1,000,000. Incorporators: M. Donehoe, S. Silvertown, John Bjork, Gus Bjork, L. G. English, Frank Lewis.

The Kootenay & Columbia Prospecting & Mining Co., Limited, of Ottawa, Ontario, with branch office in British Columbia. Capital stock, \$40,000, with shares at \$100 each.

The Swank Chief Gold Mining Co., at Ellensburg, Wash. Capital stock, \$200,000, with shares \$10 each. Incorporators: James Hamilton Lewis, Donald McLeod, L. H. Jansin, Chas. Wilen, John W. Stewart.

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market St., S. F.

FOR THE WEEK ENDING APRIL 24, 1894.

516,734.—GUN SIGHT.—F. W. Dobbels, S. F.
516,800.—KILN.—G. C. Firestone, Benicia, Cal.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Unlabeled free.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy. Price, \$4.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E. The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED
Sept. 19, 1893. }

CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.

{ FRANK BARRERE,
Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE COMPANY'S WORKS, 180 MAIN STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

— SAVED —

ON ORES DIFFICULT TO CONCENTRATE:

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILE IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, milled and assayed, show * * * from West ledge, a saving by your concentrator of 9 1/4 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

Waterloo Mills and Mines.

We present an illustration showing the larger of the two stamp mills of the Waterloo Mining Company, which are on the north side of the Mojave river, opposite the town of Daggett, on the Atlantic & Pacific Railroad, in San Bernardino county. The mill shown in the illustration runs 60 stamps, weighing 850 pounds each, with a drop of $6\frac{1}{2}$ inches 100 times per minute. The smaller mill, only a short distance away, has only 15 stamps. The capacity of these stamps is about three tons of ore to each stamp, or about 225 tons for the two mills, each 24 hours.

The mine is located about six miles north of the mills, in the West Calico mining district, about two miles west of the town of Calico, and the company has constructed a narrow-gauge railroad to connect the mine with the mills. The mine is developed by the running of various tunnels on different levels, all through pay ore. The ore body is from 10 to 85 feet in thickness and, so far as known, about 600 feet in length. No water has been encountered in the mine. The ore, it is said, runs about \$25 to the ton, or would if silver was as valuable as it was in former days.

The large mill has been shut down for three years past, on account of the high price of power and the low price of silver. It is said that the power used now costs about \$300 per horse power a year. The cost of milling the ore at present is \$4.50 per ton. With cheaper power this mine and mill could be run at a profit, even with the low price of silver now current.

The company owning the Minneola canal propose to furnish that cheaper power. Ten miles below the head of their canal there is a drop of 100 feet, which will furnish about 2000-horse power if the supply of water meets the

MILLS OF THE WATERLOO MINING COMPANY, SAN BERNARDINO COUNTY.

lowest estimates of the engineers. This power can be converted into electricity and conveyed to any mills in the valley that may need the power, and it can be furnished at one-fourth the cost of power by steam.

With this cheap power every mill in that region can be run, even with the present low price of silver; other mills can be erected and other mines opened which are non-producers to-day and must forever remain so until a cheaper power can be had.

THE inexorable law of supply and demand finds present

illustration in the silver shipments from this country to India via Russia. A mint recently constructed at Bombay is reported coining large amounts of "Mexican" silver dollars for the Chinese and Japanese trade. It also transpires that the silver-bullion shipments from the United States are mainly going to Russia and thence to India and Japan, Russia using portable mints for the coinage of rupees en route. The statement is made with some lack of authoritativeness, that "American" silver dollars are being made in large quantities in Mexico and shipped to England, and that 800,000 "English" shillings were recently imported into that country from Mexican mints, the fraud not being discovered till it was observed that the foreign mintage had a little more silver in it than the genuine article. The whole thing is mainly illustrative of the fact that water will find its level, and that some things can be done as well as others.

JUDGE HOLLEMAN at Wardner, Idaho, last week made a decision of considerable interest to mining men. In the case of Peterson vs. The Helena & Frisco Mining Co. the jury had given the plaintiff a verdict for \$11,500. There was a riot at Gsm, Idaho, in July, 1892, and Peterson was injured by an explosion that destroyed the Frisco mill. He was an employe of the company, and sued for damages by reason of injuries sustained. The trial took place at Rathdrum, Idaho, resulting as stated. Judge Holleman now sets the verdict aside, on the ground that the defendant was not responsible for the injuries, as they were caused by a mob over which defendant had no control. A new trial is ordered.

THE decline of the "sack" is evinced by a proposition to have both State conventions nominate candidates for the United States Senate.

Coxey has been found guilty of walking on the grass in Washington, D. C., and the country breathes easier.

SILVER DOLLARS are good things in one's pocket. Business Manager Eliot of the *Chronicle* of this city found one very useful last Monday. A crazy crank tried to shoot him, and nothing but a silver dollar in Mr. Eliot's trousers pocket kept the bullet from severing the femoral artery, with probably fatal result.

'Twas Carlyle who said, "We are the creatures of our environments," and invented the last word quoted to convey his meaning. The idea is exemplified by geographical surroundings, as in Oklahoma, where two men were lynched for stealing a horse, while the same day, in another part of the country, two other men were applauded for stealing a railway train, locomotive and all.

AS TO be expected in a new State, the commonwealth of Washington is not too conservative to make singular experiments. The Mineral Creek district mine owners in the western part of that State propose, so far as within them lies, to counteract the difficulty occasioned by what is deemed an insufficient currency, and have issued stock certificates in coin form, the silver in the certificates being from their own mines. They are silver certificates in every sense of the word, and combine the useful and the ornamental in an eminent degree. The price of the shares is set at one dollar each, and the coiners hold that their mintage will serve every purpose of local traffic just as well as silver dollars coined by Uncle Sam. If the fashion be followed by other silver mine owners, it will add another singular phase to a situation that already presents many striking conditions.

"RAILROADING made easy, or every man his own railroad builder," is not the title of a circular issued by a prominent official of the Populist party in Kansas, though it might with propriety be so termed. It is a plan evolved by the members of that scopy party, and proposes to build a "North and South Railroad" to connect Kansas and the Gulf of Mexico. The farmers who live along the line of the road are to build it, pay for it and own it. They are to buy hundred-dollar shares of stock and get with each share twenty-two five-dollar transportation certificates. When the road is finished these certificates will be taken as cash for one-half the price of freight or passage. Income construction bonds will be issued in shares of five, ten and twenty dollars. They are to carry five per cent interest and are to be paid out of the road's income and are to be received for all dues, with an added premium of five per cent. There is evidently money in it for somebody, but whether for the farmers or some one else remains to be proved. The plan ought to take—in Kansas,

California's Wealth.

People whose attention is not wholly occupied in contemplating the commonweal movement may find pleasure in the recent publications from the Census Office regarding California's wealth, where it is proclaimed, with becoming pride, that property in this State in 1890 (during the temporary absence of the Assessor) was worth \$2,533,733,627. That is a good deal of money, and divided pro rata among the number of us here in 1890, would give each man, woman and child \$2,097. The fact that no equal division is thus made arouses discontent in the minds of those whose individual possessions fall in cash value below that figure. The further fact that several of our fellow citizens have varying control of sums ranging from \$1,000,000 to \$20,000,000, while others of our fellow citizens are emigrating by reason of inability to earn a living, is not wholly conducive to general satisfaction, and tends to modify the joy apparent on seeing those figures.

It is not to be denied that the wealth is here. The United States census says so, and that settles it. It would, however, be better for the commonwealth were the actual average nearer the per capita indicated.

If the State wealth four years ago aggregated the sum given, it is fair to assume the true value of property in this State in 1894 totalizes the enormous sum of three thousand millions of dollars—nearly one-half as much as the total wealth of the United States when gold was discovered here.

In any event it is gratifying to State pride to observe by the following table the great and constant growth of California's wealth for forty years.

	Total.	Per Capita.
1850.....	\$22,161,872	\$239
1860.....	207,874,613	547
1870.....	638,767,017	1,140
1880.....	1,343,000,000	1,553
1890.....	2,533,733,627	2,097

An Untimely Taking Off.

The death of Colonel Robinson in London is likely to ultimately affect the problem of profitable production of tin in this State. The Colonel, as a mining engineer and mine promoter, had few superiors in California. He promoted the sale of the tin and gold mines of the Temescal range of mountains, in London three years ago, by organizing a company known as the "San Jacinto Estate, Limited." The Colonel was appointed manager of the property and proceeded to develop it by building mills and reduction works, dams for conserving water and developing the mines. J. H. Crossman took charge of the gold portion of the estate, where he developed some valuable gold mines.

The English company became alarmed at the increased tariff on tin and tin plate, the closing down of the Welsh tin plate manufactories, resulting in millions of dollars loss and the discharge of thousands of workers, and the Temescal ore proving to be unusually rich, they decided to suspend operation on these mines and pocket their loss rather than ruin the English tin interest. The stockholders refused to advance any more money by voluntary contribution or mortgage bonds and the stock reverted to the bondholders.

The Colonel returned to Europe and entered into negotiation with the bondholders and obtained an option on their bonds. He then left for New York and formed a new organization to develop this property by resumption of operations and rehabilitating the mines. At the date of the Colonel's death all arrangements had been perfected and work resumed, but his untimely death may retard operations.

Another Unique Ruling.

REGISTER HULL, of the Redding, Cal., Land Office, has made a ruling that will elicit a response not wholly in the affirmative. It is herewith appended without further present comment:

In view of departmental decision in the case of *Ferrill et al. vs. Hoge et al.*, 18 L. D. 81, all applicants for patent for placer mining claims embracing more than one 20-acre tract will be required to furnish evidence showing a discovery of mineral upon each 20 acres embraced in the tract.

This rule will apply not only to all applications which are filed in the future, but also to all applications for mining claims of this character which are now pending before this office or before the General Land Office.

In all future applications, where the claim is not taken by legal subdivisions, this evidence should appear in the report of U. S. Deputy Mineral Surveyor, and in the Surveyor General's certificate, and it would be well to set the same fact forth in the application for patent. Where the location conforms to the lines of the public surveys, this evidence must be shown by affidavit of the applicant, duly corroborated by the affidavits of two or more witnesses.

In all cases where the application has already been filed, and which are now pending before either this office or the General Land Office (whether taken by legal subdivisions or not), the evidence called for above may consist of the affidavits of claimant and two or more witnesses, fully and particularly setting forth the facts of the several discoveries and the location thereof.

Redding, Cal., April 21, 1894. SYLVESTER HULL, Register.

LEADVILLE, Col., the one time "carbonate camp," is now turning out \$10,000 a day in gold. And the free coinage of gold goes on.

Minneola Canal—A Wonderful Water Development.

An interesting water development is found on the Mojave river in San Bernardino county, on the line of the Atlantic and Pacific railroad near the town of Daggett.

This canal, the largest in southern California, has a carrying capacity of 25,000 inches, or 500 cubic feet per second, and for a distance of one mile from its head was dug by a floating dredger.

On the preceding page is an illustration, from a photograph, showing the dredger at work in ten feet of water. The bottom of this canal, through this mile of its length, lies through a water-bearing strata. The bottom of the canal at its head is 14 feet below the level of the water in the river, but none of the water of the canal, as shown in the illustration, comes from the river, as it seeps in through the water-bearing strata—pure coarse sand and gravel—through which the cut is made.

Except in times of high water there is very little surface flow of water in the Mojave river at the head of the canal, but the under flow of the stream is very great, filling the coarse sand and gravel for an average depth of 25 feet for a width of 1600 feet. In midsummer the surface flow of the river does not exceed 200 or 300 inches, but there is always a surface flow indicating that the underflow is always full.

The work of tapping this underflow has not been attempted yet. The plan of procedure, however, has been definitely settled. There will be a deep cut made across the river by the dredger. The bottom of this cut will be 14 feet below the surface of the water level at that point. In this trench, which will be 1600 feet long, will be laid a box flume 10 feet wide and 5 feet deep, so constructed that the water will find its way into the flume readily, while the sand will be kept out. This flume will have a grade of about eight feet to the mile, so as to carry off the water readily, and with it carry whatever sand may find its way into the flume. The bottom of this flume is on a level with the bottom of the canal which will carry away the water.

The main canal is completed now for a distance of four miles to Daggett, while a branch canal, with a capacity to convey about 5000 inches, is completed for a distance of four miles more.

The Mojave river has a fall of about 19 feet to the mile. Forty miles above the head of the Minneola canal, at the upper narrows, the river carries in midsummer 10,000 inches of water on the surface, besides a large underflow. Below the narrows a large extent of country drains into the river, including the Antelope valley and all the mountain streams which flow into the Mojave plateau west of the San Bernardino meridian; and while there are no surface streams which flow into the Mojave river from that section of country, there must be a large underflow that finds its way to the river and through this gap in the hills where the Minneola canal is taken out.

Engineers estimate the amount of water within reach of the Minneola canal all the way from 5000 to 25,000 inches.

Ten miles below the head of this canal is a drop of 100 feet in the canal, which will furnish several thousand horse power, the amount being dependent on the amount of water obtained. This power, converted into electricity, can be sent to the various stamp mills in this mining section, and power can thus be furnished at one-quarter the cost of the power now generated by coal. Mills which cannot be run to-day because of the high price of coal and low price of silver can thus be started up again and hundreds of people furnished remunerative employment where now a few do indifferently well.

There is a firm belief in electrical circles to-day that the time is not far distant when iron ore will be reduced by electricity instead of coal. There is an iron mountain within 25 miles of this water power which shows 20,000,000 tons of iron ore above the surface of the ground that yields from 60 to 70 per cent of iron. This iron is pronounced by the Union Iron Works and Eastern iron workers to be the very best quality for the manufacture of Bessemer steel. A railroad is contemplated from this water power to the iron deposit, and there appears to be little to hinder the building up of an iron center at this water power which shall work a revolution in the iron industry of this coast.

THE Governor of Idaho and the Knights of Labor of Wallace, in that State, have had a falling out, the labor organization denouncing the State executive. They asked him to dismiss the State mine inspector, being dissatisfied with his report regarding the fatal ore cave in the Bunker Hill & Sullivan mine, which request was refused. The Governor gave the matter full examination, visited the mine with whose underground workings he was familiar, and saw for himself that his subordinate's report was faithful and impartial, and, accordingly, stood by him, in which he did just right.

General Mining Notes.

THE Herqua Hela of Arizona paid a 6d per share dividend lately.

NEVADA DAY will be celebrated at the Midwinter Fair next Tuesday.

THE Rin Timo (Spain) copper mine paid its stockholders 7 per cent in 1893.

GOLD placers of considerable richness have been discovered in the interior of Lower California.

THE Rico (Aspen, Colo.) silver mine paid a 24c per share dividend on the 10th, amounting to \$25,000.

A LEADVILLE, Col., syndicate are sinking a deep shaft there to strike the supposed ore bodies that underlie the city.

THE total output of the Elkborn mine in Montana for March yielded \$38,264. The expenses were \$23,564 and this profit \$14,700.

A MINING stock exchange on which the mines in the Cripple Creek district will be listed, has been organized at Colorado Springs.

THE Hull & Beck mines on Lone creek, Josephine county, Oregon, were sold last Saturday to J. M. Sparkins of Seattle for \$20,000 cash.

ARRANGEMENTS have been made for the building of a ten-stamp mill on the Ford & Bentley ledges at Humboldt Canyon, Placer county.

BUILDING the railway from the White Cloud iron and copper mines, to connect with the Central Pacific at Wadsworth, Nev., will begin next month.

THE mines in Graniteville, Nevada county, employ about 100 men. The Sheep mine, in that district, has a vein of gold-bearing quartz two feet in width, assaying \$50 per ton.

THE Calumet & Hecla (Mich.) copper mine will pay a half-million dividend of \$5 per share next Tuesday. This will make \$40,350,000 in cash dividends this mine has paid to its stockholders.

It is claimed that more than fifty new gold placers have been discovered in Colorado since the 1st of January, and it is estimated that the gold output of the State for this year will exceed \$20,000,000.

ENCOURAGED by the success of the Quincy Mining and Water Co., seven or eight applications for licenses will be made to the Debris Commission as soon as possible by mine-owners in Plumas county.

AN important placer mining enterprise is reported on the Hassayampa, Arizona. A large amount of placer ground has been located, and will be worked on an extensive scale by an Eastern company.

THE gold output of the Witwatersrand, South Africa, district for March was 165,372 ounces, which makes the total for the three months ending March 31st 467,056 ounces, an increase of 153,956 ounces, or 49.2 per cent over the first quarter of 1893.

THE Great Northern Railway is reported to be under contract to forfeit \$17,000 per day for each day they cannot deliver ore from the mines of the Boston & Montana Company at Butte to the smelter at Great Falls. If so, the recent strike was a costly one for that company.

ARRANGEMENTS have been made to save ex-Senator Tabor's opera-house block in Denver from foreclosure under a \$275,000 mortgage, on which he has been paying interest of two per cent a month. Tabor is working like a common miner at the Jesus Maria mine, 300 miles from civilization in Mexico, and is said to be taking out between \$6000 and \$7000 a month.

COLORADO mining men have gone into the Meadow Lake country with the idea of working the ore. Twenty-five years ago Meadow Lake had a population of 12,000, and many fine residences and business houses, some of the latter still remaining, though in a dilapidated condition. During this excitement considerable effort was made, but the rebellious nature of the ore made it unprofitable to work it with any of the processes then known.

THE regular monthly sale of the Victor mine, at Cripple Creek, is reported this week, this time for \$550,000. The fact is, says the *Denver Mining Industry and Tradesman*, that in spite of all the reported sales, there have not been \$300,000 of Eastern money invested in and paid for Colorado mines since January 1st. Nearly all the money invested is by Denver and Colorado Springs men. The great majority of all sales reported are made only in imagination.

FROM Redlands, Cal., comes the statement that prospectors from the neighborhood of Death valley have displayed a large quantity of fabulously rich gold ore, assaying over \$2000 a ton; that several mining experts and capitalists have become interested and have agreed to furnish the needed capital to open the roads, build the mills, etc. They declare that a ledge is exposed for 800 feet, with an average depth of two feet, and that more than half a million dollars in ore is in sight.

WITH a grain of salt may be taken this dispatch from the City of Mexico: "A party, including competent geologists and mining engineers, began a systematic search for gold in the State of Guerrero, some months ago. The party has returned here, and a mine will soon be officially assigned to them. A report, given out confidentially among bankers, indicates an important gold discovery, equaling that of the gold fields of South Africa. The chief of the party declares that fully a thousand mines could be located in the new gold fields."

ONE of the largest nuggets in the history of mining is reported to have been hoisted out of the Smuggler mine, at Aspen, Col., a few days ago. Workmen encountered a huge body of ore, and in digging around it found that it was a monster nugget, and after considerable work got it to the surface intact. The chunk weighed 3300 pounds, and contained silver to the value of \$25,000. It is pronounced to be the largest silver nugget ever known, and, what is more peculiar, it is almost pure. This beats the record made in the Gibson a few years ago, when a nugget weighing 300 pounds was removed.

ONE of the largest freighting outfits in the world is used in connection with the mill at the Mammoth mine in Arizona. The distance from the mine to the mill is three miles, all but half a mile down grade. Three teams move 145 tons of ore a

day. Each team consists of 20 animals, and they draw four wagons. Three trips a day are made—usually without doubling—though sometimes one or two wagons are taken off at the up-hill half a mile. The wagons are immense affairs, almost as big as box-cars. The tires are from four to five inches wide and from an inch and a quarter to an inch and a half thick.

SUPERINTENDENT KLEPKO of the Boston & Montana smelter at Great Falls, Montana, makes a report showing that the total smelting for 18 months has been equivalent to 218,058 tons of ore and the production of 33,398,915 pounds of copper, as follows: Matte shipments, 4,781,440 pounds; pig copper shipments, 10,557,340 pounds; ingot and cake shipment, 7,246,834 pounds; electrolytic cathode shipments, 8,375,675 pounds; sundry small shipments not reported, 1194 pounds; on hand January 1, 1894, matte, pig copper, refined copper, anodes, solutions, etc., 2,358,714 pounds; furnace refinery loss in refining, 10,825,558 pounds; ingot and anodes, 77,718 pounds; total, 33,398,915 pounds. The capacity of the electrolytic refinery has been gradually worked up in capacity until it is now producing monthly 1,600,000 pounds.

General News Notes.

CHICAGO claims 1,575,000 population.

THE Midwinter Fair is a financial success.

GERMANY refuses to withdraw from Samoa.

UP to date there have been 1,300,000 admissions to the Midwinter Fair.

THE Government has at last decided there shall be no more Indian soldiers.

A FIRE at Nainaimo, B. C., last Sunday destroyed property valued at \$100,000.

THE Hawaiian royalists have hopes of overturning this Provisional Government.

PAESANT CLAVELAND says the newspapers are to blame for the Coxey movement.

THE Prince of Wales expects his son to see the inauguration of a British republic.

KING LEOPOLD of Belgium opened the World's Exhibition at Antwerp last Saturday.

THE gold-coinage circulation in this city is \$2,884,894 less than on January 1, 1894.

THERE has been a general compliance with the Chinese registry law in all parts of the country.

ALL business is paralyzed in the Argentine Republic, and a revolution is considered imminent.

SEVERAL Chicago millionaires have declared for bimetalism, and will work for the coinage of silver.

WEEK has been resumed on the Esmeralda mine, in Calaveras county, owned by John F. Davis of Jackson.

THE Baca, Arizona, grant, containing 100,000 acres, was recently sold for taxes. The amount due was \$1200.

THE amount required for pensions to United States soldiers and their heirs for the month of April was \$12,700,000.

GAULFE fears are felt in London regarding East Indian affairs; the British Government apprehends a probable mutiny.

THE St. Petersburg police have discovered a vast Nihilist conspiracy. One hundred people have already been arrested.

CONGRESSMAN CAMINETTI has introduced a bill to divide northern and central California into two judicial districts.

THE large banks of Europe are increasing their gold holdings, which are now up to about the highest point ever reached.

DESIRING to be in time, Gen. Harrison announces his candidacy for the Republican presidential nomination in 1896.

It is now thought that the Wilson tariff bill will shortly pass the Senate. Even Hill of New York is expected to vote for it.

THE San Francisco Woman's Congress has adjourned. 'Twas resolved that soap, soap and salvation were the three great requisites.

THE New York bank surplus, which is \$82,000,000 now, was \$15,000,000 a year ago, \$19,000,000 two years ago, and \$6,000,000 three years ago.

"DICK" McDONALD, the mismanager of the wrecked People's Home Savings Bank in this city, has been indicted by the grand jury and jailed.

UNEMPLOYED workmen are holding meetings throughout England demanding employment and that eight hours shall constitute a legal day's work.

THE London *Chronicle* thinks that the Coxey armies foreshadow a contest in this country "that will be almost as serious as that which arose from slavery."

AT the Cordite Powder Works near London, last Monday several thousand jars of nitrate and sulphuric acid exploded. Four persons were killed and thirty injured.

THE Secretary of the Interior has issued an order in relation to the Sierra forest reserve. All grazing of horses, sheep or cattle is forbidden, as is all cutting of timber.

THE report of the directors of the Union Pacific shows a deficit for the year on the whole system of \$2,595,841, compared with a surplus the previous year of \$2,006,767.

KALLY and his "industrials" have built a navy at Des Moines, Iowa, to go down the Des Moines to the Mississippi, thence up the Ohio and on to Washington via Harper's Ferry.

BAET HAATZ recently told an English friend that he is afraid to revisit California, as he does not wish to obliterate from his mind the California of the days when San Francisco was young.

THE treasury of Texas is without a dollar. Before the end of the year there will be a deficiency, and it is doubtful if the State will be able to meet the interest on its bonds, amounting to \$4,000,000.

AN official notice has been issued in Italy saying that, owing to the economic crisis in the United States, numbers of willing workmen have been rendered idle, and everywhere Italians have to struggle for work against American workmen. The

notice therefore warns Italians not to think for the present of emigrating to America, and especially warns such of them as go to that country to avoid Maryland, Delaware and Pennsylvania.

WILLIAM WHEALEN, of St. Peters mine fame, convicted of obtaining \$3,000,000 by floating stock absolutely valueless, was sentenced in St. Louis last Saturday to four years in the State Prison.

THE World's Fair buildings have been offered for sale at the following prices: Manufactures, \$23,350; Machinery Hall, \$12,650; Horticulture, \$7500; Agricultural, \$5000; Mines, \$4000; Fisheries, \$1500.

THE Senate Committee has reported in favor of building 12 new torpedo-boats, at a cost of not to exceed \$200,000 each, with a speed of not less than 25 knots an hour, four of them to be built on the Pacific coast.

ON the Chicago, Burlington and Quincy Company Railway, at Anrore, Ill., several locomotives are being provided with apparatus for burning oil. In a short time every engine belonging to the company will be so equipped.

THE Bear Lake Consolidated Mining Company has incorporated to develop the Snowshoe claim in the Slovan district of West Kootenay. The capital stock is placed at \$500,000 in \$5 shares, and the business headquarters are at Victorias.

AL, AR, BSC, BAR, BET, BOB, BUD, CAP, EYS, FI, FLY, GAS, GAG, GUY, HAM, INK, JOE, MAN, NAT, RST, SAC, SIM, SIP, WEX, WITT, YELL, ZIFF! No, these are not college yellies; they are names of some of the postoffices in the United States.

It is stated in Paris that the several million francs which Dr. Cornelius Herz, M. Eiffel and the trustees of the estate of Baron Reinach agree to pay to the liquidators of the Panama Canal Company will be used toward the completion of the canal.

THE new Kansas ballot law requires that "the lower limbs of the voter as high up as the knees shall be visible from the outside while the voter is in the booth preparing his ticket, the lower part of the booth having been left open for that purpose."

A boom in Russian manufacturing in general is reported. Factories, especially of machinery and railway supplies, are said to have orders for four or five years ahead, and to be working extra time. This is largely ascribed to the opening of markets in Asia.

THE Treasury Department has made a demand on the North American Commercial Company, which has the contract for the exclusive right of taking fur seals upon the Pribyloff islands in Alaska, for about \$250,000, and the matter is being argued before Secretary Carlisle and Assistant Secretary Hamlin.

CAPTAIN J. A. MELLON will next Thursday leave The Needles in the steamer Mojave, bound through the Black canyon and Devil's gats to Riverville. It has been exceedingly rare that any kind of a boat could get up farther than the mouth of the Virgin, but Captain Mellon is going to try to climb the cascades during the high water. He will have to do it with ropes and capstans.

It is stated that the mean average wages paid in the entire country in all manufacturing industries except mining and quarrying, for 1890, was \$484 per head. Among the States falling below this average were these: Alabama, \$410; Georgia, \$177; South Carolina, \$217; Maine, \$134; New Hampshire, \$101; Wisconsin, \$92. Among the States exceeding this average were Colorado, \$236; Montana, \$238; Massachusetts, \$10; New York, \$65; Pennsylvania, \$8; Wyoming, \$284.

THE Connellsville (Pa.) coal-miners' strike has been led by ladies. "Hell hath no fury like a woman scorned," and some of the women who have led in last week's scenes of violence appear to have been "scorned" somewhere, for they acted like demons, attacking the deputies and peace officers with axes. Americans are getting very weary of the murderous pranks of those savages foreigners who have no more idea of our institutions than a San Francisco policeman has of the whereabouts of a gambling game.

Personals.

J. B. HASTINGS has returned to Boise, Idaho, from Nevada.

GEO. D. ROBERTS has been appointed superintendent, and T. J. Benny, foreman, of the Mt. Moriah mine, Sierra county.

HANK SMITH, well known in years gone by on the Comstock, is now superintendent of the Grizzly mine, at Ruby Hill, Nevada.

G. E. SEABENT, superintendent of the Brown Bear mine at Deswood, died suddenly at the Grand Hotel in this city last Monday.

THE late Geo. B. Bayley, who was killed in his elevator on Davis street in this city, had insurance on his life aggregating \$165,000.

COL. E. N. ROBINSON, the well-known mining operator, died of pneumonia in London on the 28th ult. His family reside in Los Angeles.

PAT KAASIN, recently superintendent of the Gould & Curry mine at Virginia City, has been appointed superintendent of the Allison Ranch mine at Grass Valley.

CAPTAIN S. F. SCOTT goes to London in an attempt to get money to put a hydraulic plant in the square mile of placer ground he recently took up on the Similkameen, B. C.

R. D. CLARK is in the city and will shortly leave for Sonora, Mexico, where he takes charge of the lead and silver smelter of an English company. He was formerly superintendent of the Cortez mine in Eureka county, and when that closed he became superintendent of the Eureka Reduction Works.

SI RYAN, now of El Paso, Texas, is in the city. Time was when he led on Pine street, a day's transactions often involving over \$100,000. He has made considerable money in Mexico, is prominent in Texas politics, etc., and goes to England to negotiate some New Mexico mining property in which he is interested.

F. N. SPEAR, representing the Griffin Roller Mill, of Boston, Mass., is in the city, and goes to Keystone, Amador county, tomorrow to place a mill at that point. A mill is running successfully at Escondido, and three at Colton, San Bernardino county. Upon his return Mr. Spear will establish an office in the Crocker building as resident agent.

Inclines vs. Vertical Shafts.

The notes in the Mining and Metallurgy Department of the *Engineering Magazine*, says that journal, on incline *versus* vertical shafts have elicited considerable correspondence on the question. Among others, Mr. W. D. Brunton, general manager of the Della S. Consolidated silver mines and Cowenhoven tunnel at Aspen, writes that the solution of the problem in the case of that property has been extremely satisfactory. He gives the following account of the method pursued:

Two years ago the writer was brought face to face with the problem of shaft *versus* incline in a mine where the conditions were more than ordinarily complicated. Work had to be commenced upon an ore body pitching at an angle of 56° from the horizontal, which had been intersected by the Cowenhoven tunnel nearly three-quarters of a mile from its mouth and 1000 feet vertically below the surface. It was out of the question to drift through the ore body into the hanging wall so as to intersect the vein with a vertical shaft at any reasonable depth, as the shales which overlaid the ore had an unfortunate habit of "creeping" in and crushing timbers faster than any company could afford to renew them. Directly underneath the ore body, and separated from it by about 80 feet of dolomite, was an open, porous stratum of silicious dolomite threaded with a network of watercourses. If a vertical shaft were sunk from the point where the ore body was intersected by the tunnel, it would pass directly through this water-bearing stratum, which would also be intersected by every crosscut from the shaft to the ore bodies on their continuation below.

Inclines, as every miner knows, are unhandy, expensive and dangerous, and an existing 750-foot incline on the same property had proved itself such an unfeeling source of worry to the manager and expense to the company that the prospect of a second incline was as much dreaded as a flooded shaft. One day, while I was studying the question, the following idea suggested itself: "If a shaft, after having been properly sunk and timbered, should be thrown out of the perpendicular by some movement of the earth's crust, would it cease to be a shaft because it was no longer plumb, and if it was tilted over on its end instead of its side would there be any reason why the cars could not be run directly from the cages into the drifts without interfering in any way with the pump compartment or manway?" Never was an idea more eagerly welcomed or acted upon with greater good will by all concerned. The miners who began work on the shaft, especially the old-timers, who are naturally conservative, looked with some suspicion upon this plan, but before a week had elapsed they arrived at the unanimous conclusion that an inclined shaft was easier to sink, safer to work in and more convenient to operate than a vertical shaft, and that the old-fashioned incline should hereafter be considered a thing of the past.

This inclined shaft has now been sunk to a depth of 250 feet in the face of a very heavy flux of water, to extremely difficult ground, and so far without a single accident. At 84-foot intervals levels are run out from the shaft each way, down to which the tunnel cars are lowered on a cage, beneath which is attached a light steel self-dumping skip for the use of the men who are sinking, and the operations of drifting, mining and sinking go on simultaneously without in the least interfering with each other.

The incline spoken of is two-compartment and has its longer axis of cross section at right angles to the dip instead of parallel with it, as more usual. The pump compartment is above the hoisting compartment. It is locally called an "inclined shaft" rather than an "inclined winze," because, as Mr. Brunton explains, "ordinarily we speak of a winze as an underground connection between two levels; but the main opening from which these levels are driven should be designated as a shaft or incline, no matter whether it terminates on the surface or at a station a thousand feet below." The hoisting machinery is situated in a large station cut out of the solid rock on the level of the Cowenhoven tunnel. There is no intention of connecting this incline shaft with the surface, as there could be no possible gain by such a proceeding. The machinery is at present operated by compressed air, but an entire electrical equipment, including hoist, pump winch and pumps has already been ordered. The "cage" runs on wheels, but is altogether different from the Comstock giraffe.

The Phonopore System.

A company has been started in England for the purpose of introducing the phonopore system, whereby the carrying capacity of existing telegraph wires can be doubled. To meet the requirements of several of the railroad companies it has taken up the question of working a single instrument by the phonopore method. This has been successfully accomplished; and, as nearly all the telegraphists read by the sound from the needle, they will be able to use to great ad-

vantage a new sounder, worked by a handle, similar to a single-needle instrument, by which an entire circuit can be duplicated. This instrument (or a phonopore telephone for speaking, with a special bell call on the same wire,) can also be attached to the block, bell or train staff wires, without any interference with their working. If the needle instrument is preferred to this new sounder, it can be applied to existing wires, but two wires will be required. A mixed current can be formed of the two systems, sounders and needles. Phonopore telephones can be attached to ordinary telegraph and block wires, and conversation can be carried on distinctly in spite of any ordinary induction. On several occasions, when a wire has broken or became defective and the ordinary telegraph in consequence become unworkable, it is stated that the phonopore telegraph remained undisturbed, and continued to work satisfactorily although on the defective wire.

Digging Gold with a Steamer.

Extravagant stories are told about the wealth of gold sprinkled through the Snake River country in Idaho. As a general thing the gold is very fine, the particles being of so light weight as to be elusive. Save when worked on a large scale it is difficult to make good wages in recovering the gold. Numerous bars along the river would prove profitable could water be commanded for sluicing or hydraulicking. An adequate supply is hard to obtain, from the slight gradual fall of the stream and level character of the outlying lands. To overcome this lack of water, as well as to insure sufficient dumping ground, a big floating gold-saving dredge has been constructed and is now at work on the Idaho bank of the river, about ten miles above the Payette. It is a stern-wheel flatboat, propelled by steam. Substantially constructed, 65 feet long and 22 feet wide, it is equipped with a 35-horse power machine engine and boiler, and adapted in every way for navigating Idaho's great waterway. With a slight alteration, it could be transformed into a steam dredge and used to scoop up sand and gravel from the bottom of the stream. As in the past, operations are now confined to working bars out of the channel of the river.

The method pursued is to anchor alongside one of these gravel deposits, and, by the use of scrapers, bring the material to be handled within reach of the gold-washing machinery with which the craft is rigged. The gravel is scooped up by buckets attached to an endless chain. There are 48 of these receptacles on a belt 60 feet in length, and each has a capacity of about 20 pounds of dirt, which is delivered into a hopper. This is also an agitator, and the process employed may be described as a steam rocker, with the exception that it has an end motion instead of one sidewise. The gold is caught on copper plates with quicksilver. The tailings are carried off in sluice boxes by a stream of water of 150 mineral inches, supplied by a China pump run by the engine which drives all the other machinery. The gravel is worked so thoroughly that no gold escapes in the tailings that are dumped into the river. An average of 100 tons of gravel are handled, and for this work three men are employed—an engineer, one to work the scraper and another one who shovels the dirt into a pile so that the buckets can scoop up a full load. The bar now being worked covers an area of 10 to 15 acres. The gold is on top or close to the surface, and will not pay to huddle to a greater depth than 12 to 18 inches. This shows a value of 1½ to 3 cents a pan. A cleanup is made every night, and the average of the runs for the first three days was very satisfactory to Thornton Williams, the owner of the craft. He says he expects to take out upward of \$100 a day as long as he works.—*Helena Independent*.

Book Notices.

THE STATISTICIAN AND ECONOMIST FOR 1894.—The popular edition of this very useful book is received. It is compiled by L. P. McCarty and is up to date, which, probably, is praise enough to any one acquainted with Mr. McCarty's thoroughness and accuracy. The price of the book is fifty cents, and it is worth one hundred times that to any one who would keep posted on the practical and progressive in life.

MINE VENTILATION MADE EASY.—This is the taking title of a little volume which, in concise shape, gives what the majority of readers want to know on that subject. It gives rules, laws and experience, and detailed answers to 155 questions. It is published by the Colliery Engineer Co., Scranton, Pa., to whom all orders should be addressed.

THE POLITICAL ECONOMY OF NATURAL LAW.—This is the title to a timely book by Henry Wood, and tends to dispel much of the mawkish notions so prevalent regarding duty and the rights of the individual. It shows in clear, cogent reasoning that natural law governs all things mundane, and that to attain satisfactory results we must act in harmony with this natural law. It discusses labor, capital, competition, co-operation, supply and demand, socialism, corporations, industrial education, and intelligently deals with the problems of the hour. It is deserving of a place in the library of every thoughtful man, and if widely read would act as an antidote to many mistaken conceptions of rights and wrongs. The book will be sent by mail by Lee & Shepard, Boston, on receipt of \$1.25.

La Plata Gold Fields.

TO THE EDITOR:—This extensive gold belt is situated in southwestern Colorado, on the Pacific slope of the Continental divide at the south end of the San Juan range, in La Plata county, and 20 miles northwest of the city of Durango, Colorado, on the Denver & Rio Grande railroad. This gold belt extends 20 miles east and west, and 12 miles north and south. The altitude varies from 9000 to 13,150 feet above sea level. The formation is both eruptive and sedimentary and all metamorphic. The ores are strictly gold-bearing and found in fissure, contact and blanket veins. The vertical fissures vary in size from a foot to 20 feet in width and show great permanency in length, also depth so far as limited development goes. As a rule, these ores are refractory and carry a large per cent of their value in tellurides. Cyanide treatment, however, saves 90 to 95 per cent of assay value.

The contact veins carry a good average width of from 3 to 30 feet. Much of this ore is free milling on surface and will run from \$3 to \$30 per ton. It is safe to say that four-fifths of the veins and ore are refractory and carry an average value of \$10 per ton, and the average width of ore will not fall short of four feet. The blanket contact vein or deposit lately discovered, and known as the "Baker contact," reefs the mountain at an altitude of about 10,000 feet, and extends a distance of 15 miles east and west, with a slight dip to the north and into the mountain. The thickness of this immense mineralized reef or blanket deposit is from 100 to 300 feet. That portion carrying the heaviest pay is a decomposed porphyry, oxidized iron and rotten quartz. The value of this ore is not yet determined, but is said to be about \$3 per ton, and also claimed to be strictly free milling. Senator Jones of Nevada, with California associates, have taken a lease and bond on a large tract of this mineral wonder, and promise to prospect the same with a test mill of ten stamps at once. There are fully 500 lode locations made on mineral outcrop in this new camp, and yet two-thirds of the district is not prospected or staked. Fully ten prospects have shipped ton lots for tests to the Durango smelters and sampler, showing returns of from \$50 to \$500 in gold. The proposition, however, resolves itself into a low-grade treatment of large bodies of pyritic and telluride ores carrying a value of from \$10 to \$15 per ton; cheap fuel and abundance of water at hand. Thus far no mills are on the ground except a test cyanide mill of ten tons capacity, which treats the tellurides cheaply and successfully. The values being largely in the iron in the pyritic ores, require a special treatment. The rich placer bars along La Plata river a distance of ten miles proves that the origin of free gold is not found unless it be in the Baker contact. ADNA LAMSON.

DURANGO, Colo., April 26, 1894.

The Geographical Society of the Pacific.

The conference of the Geographical Society of the Pacific was held on the 4th inst. in Festival Hall, within the Exposition grounds. President Davidson delivered the introductory address, stating the objects of the congress. He was followed by Wm. Emmette Coleman of the American Oriental Society, New York. M. Borel having requested to be excused on account of illness, Capt. Everill was the next speaker, on New Guinea. The president read Capt. M. A. Healy's paper, a most interesting document. Prof. Greene, of the University of California, took the platform for half an hour, upon the flora of the coast, remarking that the field was very wide, and that much work yet remained to be done in it by the botanist. The professor stands eminent as an authority in this department. Hugh Craig, Benj. C. Wright and Theodore H. Hiltell followed in the order named.

Owing to the lateness of the hour, it was then decided to read the remaining papers at special meetings of the society, and the conference closed.

Mr. Robert Cox, a delegate from the Royal Scottish Society of Edinburgh, telegraphed from Los Angeles his regret that he was unable to reach San Francisco in time for the meeting.

The papers were all original, and all showed extended and minute examination of the subjects.

So many requests have been received by the secretary from Eastern and foreign scientists for a report of the conference that the society will probably publish a special bulletin, with all the papers, including those of Prof. Davidson, Gen. Darling, Jas. E. McGrath, Th. E. Slevin, E. J. Molera, J. McI. Wood, Capt. Chas. L. Hooper, U. S. Rev. Marine and Lieut. George Stoney, U. S. N.

The congress is another evidence that California takes her part in aiding the advance and development of education and science.

THERE is a further drop in the price of incandescent electric lamps, a Boston company now offering 16-candle power lamps for 25 cents.

Lively Times at Angel's Camp.

TO THE EDITOR:—Long before the hotly contested fight to preserve the prestige of silver had ended in failure, the mining press of the country and far-seeing mining operators predicted that the first effect of demonetizing the white metal would be to give new life to gold mining. It was quickly perceived that the withdrawal of the capital employed in silver mining must in the aggregate amount to an enormous sum, and that, in accordance with natural laws, it would seek some cognate channel where past experience and methods would be most likely to be available.

The prediction has received a most complete verification, and new vigor has already been imparted to every gold camp in the country. It is now certain, from returns received by the Director of the Mint for the first quarter of the year, that 1894 will see the largest production of gold for many years past.

In the general improvement California is getting her full share already, and by reason of the great natural advantages offered must soon be at the front of the column of progress. The present movement is gradually gaining an enormous impetus that will speedily carry the fame of her great gold belt once more to the uttermost corners of the earth. It is a singular fact, and one that has kept back the growth of gold mining in this State, that the newer the country and the less known about it the greater the attention given to it. California has been known as a gold country for so many years that it has long since ceased to cause any particular interest or comment, and the impression prevails everywhere that it is largely worked out. This is not only true outside of the State, but is largely the case—except among the best informed—at home. The world at large knows only the general fact that hundreds of millions of dollars of the shining metal have been produced from her mines, but does not know that nearly all of these millions came from the placers and surface diggings, the product merely of that superficial erosion caused by the infinitely slow processes of the elements, but which have barely touched the original sources and storehouses of the vast treasures remaining. While the aggregate product from widespread sections has been enormous, it is but a fraction of the wealth remaining in the quartz-ribbed vaults of the eternal Sierras.

But, after all, the fact remains that newer countries with far less mineral resources and but few, if any, of the great natural advantages with which California is favored, have attracted the gold-seekers, while her countless lodes of immense extent and richness have lain idle and neglected, the comparatively few quartz mines of the State not really constituting a beginning when compared to the immense possibilities. It is the velocity given by the first great "rush" or "stampede" that advertises a new mining district or country and attracts the men and money that finally build it up. California had one inning in this line and startled and fascinated the world, but the maximum development was along the lines of placer and hydraulic work, which the hostile agitation of the anti-debris people and the subsequent legislation practically paralyzed at the very summit of success. But, unless all indications are deceptive, another development, still greater and more lasting, is impending which, when it reaches flood tide, will again attract world-wide attention and once more fill the mining districts with eager life and activity, though it must be rather a slower process than when the California gold fields added the charm of novelty to unrivalled richness.

Though the mixer of the Golden State has carried placer and hydraulic mining to the top notch of scientific success, and become the standard of the world in that branch, yet, in accordance probably with the great law of compensation, he is an infant in quartz work, and the miners of Colorado and Montana would be inclined to smile at many of his methods and ideas. But in this, as in all things, there are exceptions, and these seem particularly brilliant in California because of the dead level of general inefficiency that surrounds them. Among the few who constitute these exceptions, and whose natural ability, sound judgment and great foresight have led them to systematic and scientific work, resulting in great financial success, is Alvinza Hayward, who has stuck to California gold properties and patiently developed their capacities and peculiarities while many of his contemporaries were scattering their investments from Mexico to Alaska and into all the mining States of the Union.

About six years ago Mr. Hayward bought a controlling interest in the Utica mine, at Angels, which had been a perfect graveyard for mining capital, though a rich streak at one time is said to have enabled James G. Fair to unload it for the "stake" that afterward grew to such round proportions in other mining ventures. Mr. Hayward's theory has always been that mining on the mother lode, to become permanently profitable, must be carried on in depth, so that he immediately commenced sinking on the

Utica; and at 800 feet was rewarded with a rich body of ore of immense size and which has gone on steadily widening and increasing in value until to-day the mine is conceded to be the richest on the coast, and probably in the world. That was the beginning. It may be said to have been the origin of successful quartz mining in Calaveras. "Nothing succeeds like success," and of course others were soon profiting by good example, while Mr. Hayward and his associates were also spreading out and covering in more ground. So, year by year, this company and the others that have followed in the lead have been quietly working away, turning out monthly dividends with a certainty and regularity that have gladdened stockholders' hearts and astonished all investigators, until now the district is on the eve of an inevitable and well-founded boom. It is needless to say that the owners of these mines have done nothing to attract attention to the country. They are well satisfied to keep quiet and gradually acquire, at low prices, all the mining land possible; but things have gone too far for that condition of affairs to exist any longer, for too many people have taken in the situation to keep the news from spreading.

ANGEL'S CAMP.

The center of all this activity and prosperity is Angels, or Angel's Camp as the old timers still prefer to call it. The Utica and several other of the best mines are located right in the town and of course the place has kept pace with the growth of the mining interests. It is unquestionably the liveliest and most thriving town on the Pacific coast and probably in the United States. It is a most cheerful place to visit in these days of dullness and universal depression. The streets are crowded always, but especially of evenings, when the miners quit work and everybody flocks in from the surrounding country, when the jam would hold its own very well with lower Market street when the Midwinter Fair crowds focus at the ferris. Not a vacant storeroom or office can be had for love or money. Everybody is busy and contented, and the whole place wears an air of conscious thrift and success.

The muffled boom of blasting comes in from the hills and gulches on every side, while the roar of stamp mills is heard in all directions. Bustle and life abound; saloons are thick and crowded, hotels overrun until it is often impossible to get a room, and all the other symptoms are in plain evidence that indicate the fever that culminates in a "boom." Already the mining operators, always the first to scent a mining development from afar, are on the ground and more coming every day. There is another feature about the place that arrests the attention of a stranger as quickly as the great activity of its people, and that is its tremendous population of dogs. It is something wholly unique and appalling, for a very superficial calculation shows that it must take as much food again to supply this howling, tearing, fighting, parti-colored mob as for the balance of the inhabitants, and as all supplies have to be hauled from the railroad, 20 miles away, it must be rather an expensive item of expenditure. It is not known if there is any local rule or custom that requires every man, woman and child to own at least one dog, but the facts seem to point that way.

The Utica and the other mines being worked by the same company—the Stickles, Gold Cliff and Talloc—are now employing about 700 men, their pay roll for last month being in the neighborhood of \$65,000. This alone would support a good-sized town, but there are many other mines and mills in constant operation which contribute to the growth of the place. The population is now stated to be over 3000, though the latest California gazetteer, published barely a year ago, credits it with only 700. In addition to the mines already mentioned, with a milling capacity of 200 stamps, there are the Blair mine, ten stamps; the Oshorn, ten stamps; the Maltman, five stamps; the Calaveras, twenty stamps, and the Jones and Porter, forty stamps, all running day and night and paying regular dividends.

Prospecting is going on with a vigor unknown since the great placer days, and new strikes are reported every day, most of this work being done, however, in the old locations. Four of these old claims, lying together and recently relocated by A. O. Viertong, have just been sold to Dr. Burd of San Francisco and his associates, and they have announced the immediate construction of a hundred-stamp mill and the commencement of operations on a large scale. The Calaveras Company, a rich English corporation, which has been prospecting their property extensively with a 20-stamp mill, have just made public their intention of adding 80 more stamps to their plant at once and the beginning of regular mining with a large force of men. The Hayward Company talk of adding 60 more stamps to the Talloc mill, making it 100, as they have now prospected the mine to a depth of 1000 feet, and it is claimed that it is to be a far greater property than even the old Utica.

These great improvements, together with the usual

rumors and vague whispers of rich strikes and proposed developments, always so plentiful in an active mining town, keep every one on the *qui vive* of excitement—the bread of life to the miner and a stimulating tonic that energizes the whole community.

The future is certainly very promising for this hustling little city, for its present prosperity seems merely the beginning. An old and widely experienced mining man, who has recently gone over the country very thoroughly, claims that "the country is practically a virgin gold field, almost wholly untouched," and it is assuredly true that the mining industry is barely in its infancy. With the few notable exceptions mentioned, the entire region is practically unprospected. With the great mother lode crossing the full width of the county, and everywhere visible in enormous croppings, and a network of lodes, veins and stringers in every direction, yet there has been almost no work done upon them, and it is probable that not one-fourth of the veins have been discovered, let alone explored.

But the great and ever-increasing success of the mines already opened is having a wonderful effect upon the old inhabitants as well as the fresh arrivals, and old shafts and tunnels, many of them started in the days of '49 and early '50s, are being cleaned out, retimbered and put into shape for working, while here and there a real prospector is stumbled upon patiently searching for new locations, though as yet this class is very scarce. Enough, however, is being done in new directions to insure an immense increase in active operations during the coming summer, and the great expansion of the mining business here will undoubtedly prove a starting point for a rapid and prosperous growth throughout the entire gold mining section of California, without question the greatest in the world, not even excepting the much lauded and so-called "Golden South Africa."

EUGENE B. CUSHING

Angels, May 9, 1894.

Carbonate of Zinc Deposit.

TO THE EDITOR:—In your issue of March 24th you describe the process of Dr. D. L. Bartlett for treating zinc-lead ores, and thinking that it might be of some importance to the mining interest of our country I give you the following facts:

There is a very large deposit of carbonate of zinc, carrying a small per cent of lead (not to exceed 3 per cent) and from 35 to 50 ounces of silver per ton, situated about 15 miles from the railroad, with a good wagon road to the mine, and which is at present not held by any one, but is subject to location in the aragona.

Something over a year ago I was sent to make an examination of the property and did so, with a view of getting capital to establish works at San Francisco to make the deposit available, but the hard times coming on, the business was allowed to go by default. The deposit is extensive and conveniently situated for working; it rises above the road many hundred feet and shows hundreds of tons that can be extracted by simply breaking it down, the ledge in places being 40 to 60 feet wide.

Samples were taken to San Francisco and examined and assayed by Prof. Hanks, which gave 27½ per cent of zinc.

Here is a field for the profitable investment of capital, as a plant to utilize the product of the mine would not cost to exceed \$5000 that would handle 25 tons per day.

The ore exists as a carbonate and the process for treating it would consist of a few retorts placed one above the other with a connection between them, so that the charge from the upper retort could be drawn to the one below after the carbonic acid had been expelled. The rationale of the process consists in first driving off the gases at a lower heat and then subjecting the ore to a heat sufficient to volatilize the zinc. By this mode we get a valuable pigment for paint, quite as good as that made from the metal, and at a cost so trifling that it would have a big profit.

A summary about as follows would be taken as a safe one:

Cost of transportation from mine to San Francisco, including hauling, mining and railroad charges.	\$15.00
Coal, as fuel.	1.00
Iron, as a flux.	1.00
Labor.	2.00
Interest and incidentals.	1.00
	\$20.00

PRODUCT—	
Oxide of zinc, 700 lbs. at 4c.	\$28.00
35 ozs. silver (taking the lowest assay value and market price) at 60c.	21.00
	\$49.00

Profit per ton.	\$29.00
25 tons per day at \$29.00 per ton.	\$725.00

I have not deducted anything for smelting the metal that comes from the ore in the retort, but as that only represents 100 lbs. out of every ton it only amounts to about \$1 per ton of ore handled, and the margin of profit is great enough to deduct it several times over.

I have only taken the metallic basis as the amount of

oxide of zinc, and yet there is an increase in their weight by oxidation, so that my item of expense is ample to cover it all. The manufacture of oxide of zinc on the coast would be a paylog enterprise even if manufactured from the metal, but a large saving can be effected by the use of the ore above referred to, while the silver would leave a profit over all expenses.

I took much interest in this enterprise and spent valuable time to get at the facts, but the capital could not be had at the time and the matter was left for future developments. If it will interest any one of sufficient capital to start works to reduce the ore and produce the pigment, I will be pleased to give them all the information I can and aid in every way to get so important an industry established without any consideration or remuneration whatever. The oxide of zinc will find a ready sale all over the coast from Washington to Mexico as a pigment for paint, as it is largely consumed by all paint grinders.

So many are seeking gold mines, and are quite willing to invest even large amounts, that I am at a loss to understand why such a proposition as this will not be taken up, as it is entirely without risk and sure to make more money than most of the mines now being worked.

I have not gone into the reactions that take place in this treatment, but will give the chemical changes that occur to any one desiring to look into the matter.

JOHN T. DAVIS.

Isujoba, Sonora, Mexico, April 21, 1894.

The Limitations of the Gold Stamp Mill

IN THREE PARTS—PART II.

Continued discussion of the paper of Mr. T. A. Rickard, read at the Chicago meeting of the American Institute of Mining Engineers, August, 1893.

On the use of double-discharge mortars much has been said; but, in spite of frequent recommendation, they have gone out of favor. The main point to be considered in this connection is, that the use of a back-discharge weakens the force of the issue through the front screen, and so gives results less than would be, at first glance, expected. There is another objection, especially in dry regions, to the double-discharge, namely, the consumption of water is considerably greater. This in itself proves the smaller force of the splash. At Clunes (Victoria), in the use of double-discharge mortars, the consumption of water is from 8 to 10 gallons per stamp per minute, while at Ballarat, an adjoining mining district, with ordinary single-discharge mortars, it is usually at the rate of 5 gallons. The crushing capacity is 2½ tons per stamp in the former, and 2 tons in the latter case.

The minimum loss of quicksilver, which has come under my notice, was at the South Clunes United Mill at Clunes, where it was 5½ grains per ton of ore. The maximum was that of the Caledonia Mill at the Thames, New Zealand, where one ton of quicksilver was consumed in two weeks by 20 stamps.

Table III indicates the loss at a number of localities.

In addition to the figures of cost of milling given by Mr. Olcott, I may contribute the data contained in table IV.

TABLE III.—CONSUMPTION OF QUICKSILVER.

DISTRICT	Loss per ton of Ore.			Remarks.
	Minimum.	Maximum.	Usual.	
Gilpin county, Colorado.....	3.7 dwts.	9.8 dwts.	5 dwts.Inside and outside plates
The Thames, New Zealand.....	12 dwts.	25 dwts.	14½ dwts.Outside plates. Grinding in pans
Clunes, Victoria.....	5½ grains	5½ grains	5½ grains	No plate amalgamation. Wells and barrel
Otago, New Zealand.....	5 dwts.	8½ dwts.	7 dwts.Outside plate amalgamation
Ballarat, Victoria.....	2½ dwts.	5½ dwts.	5½ dwts.Outside plates and wells
The Ovens, Victoria.....	4 dwts.	19 dwts.	9 dwts.Outside plates. Grinding in pans
Bendigo, Victoria.....	6½ dwts.	9½ dwts.	7 dwts.Outside plates and wells
Charters Towers, Queensland.....	60 dwts.	100 dwts.	80 dwts.	Outside plates. Grinding in series of pans
Amador, California.....	2½ dwts.	6½ dwts.	4½ dwts.Inside and outside plates
Grass Valley, California.....	11 dwts.	15 dwts.	12 dwts.Inside and outside plates

TABLE IV.—COST OF MILLING.

MILL.	Power.	Stamps.	Cost.	Year.
Hidden Treasure, Gilpin, Colorado.....	Steam, and water which is free of cost	75	\$0.78	1891
Gover, Amador, California.....	Water which is bought.....	20	0.53	1893
North Star, Grass Valley, California.....	Water, bought.....	40	0.81	1838-90
Wildman, Amador, California.....	Water, bought.....	30	0.47	1891
Britannia, Ballarat, Victoria.....	Steam.....	40	0.56	1891
South Clunes United, Clunes, Victoria.....	Steam.....	50	0.64	1890
New Chum Con., Bendigo, Victoria.....	Steam.....	30	0.68	1891
Excelsior, Charters Towers, Queensland.....	Steam.....	50	1.95	1890
Saxon, Thames, New Zealand.....	Water, bought.....	33	0.88	1892
Mountain, Thames, New Zealand.....	Water, bought.....	40	0.90	1892
Phoenix, Otago, New Zealand.....	Water, free.....	30	0.70	1890
Morgan, South Wales, Great Britain.....	Water, free.....	40	0.20	1891
Phoenix, Wynad, India.....	Water, free.....	20	0.84	1884
Mysore, Kolar, India.....	Steam.....	90	3.05	1892
May Con., Johannesburg, South Africa.....	Steam.....	20	3.15	1890
Jumpers, Johannesburg, South Africa.....	Steam.....	100	2.40	1890
El Gallo, Caratal, Venezuela.....	Steam.....	60	1.08	1891
Treadwell, Douglass Island, Alaska.....	Water, free.....	240	0.85	1893

In each of the cases contained in this table the cost of transportation is omitted. The cost of water power in California is usually about 20 cents per miner's inch (or 1.57 cubic feet per minute). At the Gover mill this expense amounts to from 18 to 20 cents per ton of ore, while at the North Star it is 31 cents, so that, including the cost

of power, the milling was done at these two thoroughly representative plants at the rate of 33 and 50 cents per ton respectively. The ore crushed at the North Star is particularly hard. The use of grinding and amalgamating pans increases the cost at the mills of Charters Towers (Queensland) and the Thames (New Zealand). At the Phoenix (N. Z.) no plates, but blankets only, are employed.

The question of the turning of the stamp is referred to by Mr. Argall and Mr. Olcott. The amount of the revolution is dependent upon the height and speed of the drop, and upon the amount of grease upon the cam. Occasionally, when the cam surface has too much lubricant upon it, the tappet slips past without causing any observable turn. At four different mills, working under dissimilar conditions, I have noted the turn to be as follows:

MILL.	Stamp, lbs.	Drop, inches	Speed $\frac{1}{2}$ min.	Amount of Turn.
Hidden Treasure, Gilpin Co., Colorado.....	550	17	31	1 to 1½ revols. per drop.
Garden Gully United, Bendigo, Victoria.....	780	9	80	1 revol. in 4 to 9 drops.
Harriettville, Ovens, Victoria.....	700	8	70	1 revol. in 4 to 7 drops.
North Star, Grass Valley, California.....	850	7	84	1 revol. in 5 to 8 drops.

As to the practical effect of the turn there is evidently much question. If the stamp turns as it is being lifted, it must continue to turn slightly after the cam has passed from under it. That the result, as far as it affects the ore upon the die, is insignificant in most cases may be admitted; but it is supplemented by another factor, namely, the inequalities of the surface of the shoe. The effect of the latter is various, sometimes causing the stamp to move bodily out of the vertical (a movement soon checked by the guides), and at other times causing a revolving motion. The die, of course, also wears unevenly, but as it is covered with ore, this fact has not the importance in this connection which must be allowed to that "cupplug" of the shoe which promotes an irregular grinding action against the ore.

The use of a modern form of the arrastra at the Pestarena mill is quoted. The extraction, according to the report of the company, was 81 per cent in 1888-89, and 78 per cent in 1889-90. The loss of mercury in the respective years was 230 and 234 grammes per metric ton, equivalent to about 7½ pounds per short ton. The capacity of each mill was two-thirds of a ton per day. No doubt machines of the arrastra type will, in many cases, give the best conditions for promoting amalgamation; but, as compared with the stamp mill, most machines of the grinding class have a very small crushing capacity, and consume a great deal of mercury.

In commenting upon my description of the Gilpin county milling practice, Mr. Argall has made a series of verbal criticisms which seem to me unnecessarily hypercritical and occasionally unfair. I reply to them only so far as to make my meaning plain, using the numbers employed by Mr. Argall.

(1) He points out "that if the pyrites remained longer in

ore inside the battery longer than is necessary for pulverization, in order to give more opportunity for amalgamation. The ore is mainly pyritic, and it is the pyrite that is immediately associated with the gold, therefore I spoke of the pyrites remaining in the mortar longer than was necessary for crushing purposes, but not "longer than the other portions of the ore."

(2) My statement that "the long drop gives the interval of time required to allow the settling of the fine gold" is true. All the gold of the ordinary Gilpin county ore is fine, and because it is fine, the present system of reduction is employed. The character of the amalgam, and the low retort yield, are indicative of the minute subdivision of the gold particles. There was no comparison made or intended by me between the "coarse" and the "fine" gold in the ore, and Mr. Argall controverts his own imagination.

(3) It is quite possible to comprehend my statement without supposing the gold to be endowed with "the potentiality of locomotion." The deep discharge and the roomy mortar, both "jointly" and "severally" afford a chance for the gold to get out of the way," because the depth of the one and the roominess of the other prevent the making of a violent splash, such as is produced in a narrow mortar with a shallow discharge; and the smaller force of the splash prevents the rapid exit of the pulp through the screen, and enables it to remain inside, so that the gold which it contains may be collected by the mercury lying at the bottom of the mortar, and by the amalgamated surface of the inside copper plates. If the discharge were shallow, and the mortar narrow, the gold could hardly get out of the way of the falling stamp without making its exit through the screen, and therefore, in the case of ore carrying gold in the finely divided condition which characterizes the Gilpin county mill stuff, it would not be possible to save more than a very small percentage inside the battery. It is indeed true that in California and Australia a good proportion of the gold is often arrested inside the mortar, but such gold is considerably coarser than that caught upon the amalgamated tables outside; and, moreover, the ore itself is of a different nature, and the gold is essentially less fine than that treated by the mills of Gilpin county.

Referring to the interval which occurs between the successive drops of the stamp and the pause which is thus occasioned, enabling the particles of gold to settle and become amalgamated, I remarked that "in a Colorado mill the interval is two seconds; in California it varies from three-fifths to two-thirds of a second." This was said in comparing the relative frequency of the agitation to which the water in the mortar is subjected by the action of the falling stamp. It is quite unnecessary to point out that there are five stamps in each battery, and that therefore the duration of the interval should be divided by five. If we carry out this line of reasoning we shall conclude that there is no time of absolute quiet, for when none of the five stamps of any particular battery are falling, the water is still being agitated by the concussion produced by the stamps falling in the mortar boxes on either side.

As regards the warming of the water in the mortar by the conversion of wasted energy into heat, I did not consider it very considerable; but, it may be, nevertheless, sufficient to add to the solubility of certain portions of the ore—as, for instance, partially oxidized pyrite. A careful test made at the Gover mill, Amador, California, gave the following results:

TEST OF THE TEMPERATURE OF THE WATER BEFORE AND AFTER LEAVING THE BATTERIES, JAN. 10, 1894.

Time.	Before.	After	Temperature of air.
8:30 A. M.....	37.0°	40.6°	46° F.
8:30 A. M.....	38.0°	40.5°	46° F.
8:30 A. M.....	38.6°	40.5°	46° F.
3:30 P. M.....	45.0°	40.0°	50° F.
3:30 P. M.....	43.0°	46.0°	50° F.
3:30 P. M.....	43.5°	44.5°	50° F.
3:30 P. M.....	43.0°	45.0°	50° F.
4:30 P. M.....	42.0°	44.0°	48° F.
4:30 P. M.....	42.0°	45.6°	48° F.
4:30 P. M.....	42.0°	45.5°	45° F.

(To be continued.)

THE Austin Reveille has a story of a rancher who is said to be killing range horses and feeding his hogs upon the carcasses. He has Indians to do the killing by shooting the horses with a rifle. The horses are very wild, but the Indian slips upon the hand, and succeeding in shooting one horse down, the others throw up their heads and tails and plunge about in dismay, every few minutes going closer to the dying animal, when another is brought down, and so on, until lately one Indian killed in a few minutes one entire band of twenty-seven horses.

THE walls of Babylon were 350 feet high and 100 feet thick at the base.

DELAWARE is the lowest State and Colorado the highest above sea level.

The Economic Advantages of Smelting Pyrites by Utilizing their Fuel Qualities.

That pyrites can be ignited, and after ignition will continue to burn, has long been known; and advantage is taken of this property by acid manufacturers, who burn them in kilns without the use of any fuel whatever, subsequently converting the fumes into sulphuric acid. But it has remained for modern science to show that these pyrites can also be made to replace, to a large extent, the coke ordinarily used in smelting ores of copper, nickel, gold, etc.

This method of smelting sulphide ores, which consists in making available the heat stored up in their iron and sulphur contents, is what is technically known as pyritic smelting, and has been thoroughly discussed in recent scientific publications (notably in the *Bergund Huettenmaennische Zeitung*, Vol. LIII, page 42, and in the *Chem. Zeitung*, 1893, No. 99; 1894, No. 9; and in the *Engineering Magazine*, April, 1894), so as to warrant taking up further valuable space in this journal. Any one wishing to inquire further into the scientific and technical points involved in this method of ore reduction can address Mr. W. L. Austin, Denver, Colorado, but the special object of this present article is merely to emphasize some of the pronounced advantages of pyritic smelting when applied to suitable ores, as compared with other processes of ore reduction. The first point which merits attention is the great saving of both time and money effected by

AVOIDING THE ROASTING OF ORES.

It is well known that in the ordinary methods of treating pyritic ores, such, for instance, as the great pyrites deposits of Spain and Portugal, or those of Norway and South America, the first step in all such operations is the roasting of the ores. Great heaps of the mineral are piled up and set on fire, and allowed to burn slowly until the pyrites are converted into oxides, which are subsequently smelted or treated in some other way, for the extraction of their valuable contents. This burning—or roasting, as it is called—requires weeks, and sometimes months, for its completion, during which time large amounts of capital are tied up in these heaps and therefore unproductive. In the case of large and important mines, the year's interest account on the money lying idle in roast heaps becomes a factor of no small importance. Therefore, pyritic smelting, which method takes the raw sulphides from the pit's mouth and with no preparatory treatment whatever dumps them into a blast furnace in pieces of any size that a man can lift, and within twelve hours turns out a concentrated product ready for the market, offers advantages so manifest as hardly to require comment. All the cost of labor employed in breaking, piling and burning the raw ore is saved, and in one operation (or where high concentration is desired, in two operations) the low grade ore is converted into a product (matte) which is only reached in the older methods by breaking, roasting and repeated smeltings. A second very material advantage gained by pyritic smelting is the

INCREASED CAPACITY OF FURNACES,

For, by utilizing the fuel qualities of the ores themselves, very much more material can be run through a furnace of a given size than where tons of coke and charcoal must be consumed together with the ore. It requires time to consume carbon fuels, and where these are omitted from a furnace charge it stands to reason that more of the paying material (ore) can be added to the charge. Actual practice has clearly demonstrated that when a blast furnace is operated with pyrites instead of coke, from 50 to 100 per cent more ore can be passed through it than by the old methods of smelting. This would naturally be expected, because the sulphides of iron, etc., are extremely fusible, and softening before the high temperature produced by the combustion of the iron and sulphur, they melt down rapidly and burn before the powerful air blast used, creating an intense heat, which in turn melts the batch of ore next above. Furnaces with an area at the tuyeres of 30 square feet (a size now commonly used for smelting purposes in western America) will smelt from 150 to 200 tons of raw sulphides in 24 hours. The labor necessary around a blast furnace is comparatively small, so that handling such large quantities of ore in so short a time and at so small expense necessarily reduces the cost per ton of ore smelted to the minimum, and permits the handling of very low grade ores.

Under favorable conditions the cost of producing concentrated matte from raw sulphides, taking the latter from the pit's mouth and handling 200 tons per diem, will not exceed \$1.50 per ton of ore. It is generally admitted by metallurgists that the most complete extraction of metals from their ores is accomplished where it is possible to employ fusion, and therefore the smelting process is always adopted where admissible. But very often the cost of fuel (coke, etc.) is so great as to preclude the

use of this method of reduction, and therefore a method of smelting in which

NO COKE OR CHARCOAL IS USED

Is a desideratum. That pyrites in itself contains sufficient calorific power to support unaided a smelting fusion has been so clearly proven as not to admit of argument at the present time, and it would be manifestly a disadvantage to employ two separate and distinct classes of fuel at the same time and in the same operation; for there would necessarily be some difference in the combustibility of the two materials, and one would burn before the other, which would lead to disturbances in the working of the apparatus. Where sulphides and coke are both burned in a blast furnace, the latter burns first, and the heat thereby produced only serves to melt down the former, which runs through the furnace in the form of monosulphide and comes out otherwise unaltered. This is a self-evident proposition when one stops to consider the chemical reactions which take place, for the coke being a simple element unites readily with the oxygen of the blast, whereas the pyrites, which are compounds of sulphur and iron, must first have their elements dissociated before they can combine with the oxygen. This is the explanation why sulphide of iron (matte), when melted in a furnace with carbonaceous fuel, comes out in the same form as that in which it is put in, practically in the same quality and in the same amount as charged; and it also explains why it is wasteful and unnecessary to use coke in pyritic smelting, when there is sufficient sulphide of iron in the furnace charge to give the

THE ELLIOTT-LINCOLN DYNAMO AND MOTOR.

requisite heat for the operation. With a proper arrangement of the ores, fluxes, etc., concentrated matte can be produced without the aid of carbonaceous material in the charge, and therefore the saving in cost of treating ores over other methods is apparent, the fuel item alone being often an impassable barrier to the working of some low-grade mineral deposits.

One of the first things to be considered in all metallurgical operations is obtaining a

HIGH PERCENTAGE OF EXTRACTION,

And this can be safely counted upon in pyritic smelting when comparing the various processes available in a given case. In this process we have to deal firstly and mainly with the sulphides or arsenides of iron in one form or another, and secondly with the metals—copper, nickel, gold, silver, etc. Now we know from experience in Bessemerizing mattes, etc., that as long as the sulphide of iron is present it alone is slagged off, being far more easily oxidizable than the latter metals. The same principle holds good in pyritic smelting. The sulphur burns off, or combines with the copper, nickel, etc., while the iron is oxidized to the protoxide, in which form it combines with the silica present to form a slag. As long as sulphur is present the copper, nickel, etc., on account of their strong chemical affinities to this element, necessarily unite with it to form sulphides, and, therefore, unless the concentration is carried too far, the slag will be found to be practically free from these metals. Sometimes it is desirable to divide the operation into two parts, concentrating up to a certain point in the first smelting, and then carrying the treatment to a finish in the second. If the useful or precious metals go into the slag in any quantity in the second operation, this slag can be returned to the first smelting, where it is of service in assisting in the even operation of the furnace. Experience has demonstrated that the saving of the useful and

precious metals in pyritic smelting closely approximates, if it does not equal, that obtained in the older methods of smelting.

One of the most disagreeable features connected with the treatment of large quantities of sulphide ores by the methods so long in use is the enormous quantities of noxious gases turned into the atmosphere, devastating large tracts of country and causing damage to vested interests. Any method of handling sulphide ores by which the

SULPHUROUS FUMES CAN BE UTILIZED,

Or at least rendered harmless, would in itself be a vast improvement. In pyritic smelting, almost all the air is utilized in oxidizing the sulphur and iron, so that the gases escaping from the tunnel head are in a concentrated form, and can be made available for manufacturing sulphuric acid, or readily condensed in suitable towers and thereby prevented from escaping into the air. That these gases are very highly concentrated is evident from the fact that they are often tinged with the yellow color of the sulphur itself, or burn on the top of the charge, and they are therefore in a suitable condition for acid manufacture.

It was considered necessary, when this system of smelting was first introduced, to employ costly (as well as cumbersome) hot-air stoves to heat the blast before it entered the furnace. This apparatus is no longer considered essential, and the first cost of plant is greatly lessened by their omission. Further improvements recently introduced, and for which patents are now pending, will enable the use of much smaller furnaces than were at first thought possible, and provide miners with the means of working small batches of sulphides at a very low cost per ton.

The Elliott-Lincoln Dynamo and Motor.

The cut shown herewith illustrates the type of motors and dynamos manufactured by the Elliott-Lincoln Electric Company of Cleveland, Ohio.

As will be seen, the machine, which is four-poled, has but two field coils. The two direct poles are on a vertical line, and the two consequent poles are on a horizontal line. It will be noticed that all the iron on the outside of the frame is of one polarity, and consequently there is no external magnetism; in other words, it is ironclad.

The commutator has in it 91 segments, and is provided with only two brushes, set at an angle of 90 degrees on top of the commutator.

Combination brushes are used on the machine for all voltages. The back of the brush, or that part which the commutator comes to first in its

revolution, is of copper, enabling the current to be carried to and from the commutator without the loss incurred by the use of carbon brushes, due to the high resistance of carbon. The other side of the brush, however, is of carbon, which serves to wipe out the spark and prevent either commutator or brush from cutting under any circumstances.

The bobbins are wound in a lathe on a form. As the coil is being wound it is thoroughly saturated with an insulating varnish. After removing from the form the coil is taped all over with a double layer of adhesive tape.

After the proper number of coils has been obtained, they are laid on the armature, which has been previously thoroughly insulated.

The method employed of laying on the bobbins corresponds to the horizontal method of winding, by means of which the difference of potential between any two bobbins adjacent to each other is only a few volts.

After the armature core has been covered with one layer of bobbins, a layer of insulation (consisting of canvas and oiled band paper) is laid over it and the second layer of bobbins is put on. Then follows the banding required in any drum armature.

MUCH time and money have recently been spent in scraping off the oil that found its way from the condensers and feed-water into marine boilers. It is believed that a perfectly efficacious remedy is to put into the boilers some redwood sawdust, which by attrition cuts off the oil, and by affinity absorbs it, leaving the whole as a loose granular deposit in the bottom of the boilers. This fact was apparently established by a late experiment in which a battery of boilers badly oil-coated were perfectly cleaned in a few days with no expense or detention whatever.

THE human family is subject to 45 principal governments.

Scientific Progress.

The Earth Out of Repair.

Observations are to be made simultaneously at Washington and at Manila, in the Philippine islands, which is almost directly opposite Washington on the other side of the globe, to see what is the matter with the axis of our planet. Observations show that for some time the earth has not been revolving on that important, if imaginary support, as she has done for centuries, and scientists have decided that it is time to find out if possible what it all means. Those who have studied the subject declare that if the variations continue, in the course of some very long and very indefinite period, we shall have an Arctic climate, and the latitude of every place on the globe will be changed, and our geographies will be useless.

An equatorial telescope has been finished and sent out to Manila, and before long, diligent inquiry will be made into the whys and wherefores of the peculiar performances of old Mother Earth. While one set of scientists is trying to find out about the axis, another party is endeavoring to find out why the magnetic needle varies so.

Lives Sacrificed over Engineering Constructions.

According to M. Eiffel, the cost of any big engineering work in lives can be estimated with at least as much accuracy as the cost in money. "It has been ascertained," he said, "by statistical observation, that in engineering enterprises one man is killed for every million francs spent on the work. If you have to build a bridge at a cost of 100,000,000 francs, you know that you will kill 100 workmen." The argument, while rather an ingenious one, is not, we believe, borne out by facts. Take the Eiffel Tower, for example. Six and a half millions worth cost only four lives. The Forth Bridge, on the other hand, a contemporary points out, cost 45,000,000 francs, while the lives of 55 men were sacrificed in connection with its construction. Then in regard to the Manchester Ship Canal, only 130 lives have been lost against an expenditure of 325,000,000 francs.

Smokeless Powder.

This explosive compound consists of a combination of an ammonium chlorate, potassium or sodium picrate, and ammonium picrate. Ammonium bichromate gives good results and is very stable. The materials are mixed in the proportion of about 20 parts by weight of ammonium bichromate, 25 parts of potassium picrate, and 55 parts of ammonium picrate. The potassium picrate is first ground in a moist condition until it is sufficiently fine; the ammonium bichromate and ammonium picrate are ground separately, and mixed in a sufficiently damp condition until they are intimately incorporated. The potassium picrate is then mixed with these ingredients in a powder mill. The mass is then placed in a press and pressed into cakes, these cakes being afterward broken up and granulated, after which the powder is dried at a temperature of from 100° to 125° F.

SINCE Professor Lippman first showed his picture of the solar spectrum to the French Academy of Sciences some three years ago, his experiments have been continued with results that promise an early solution of a perplexing problem. His recent pictures include a stained-glass window, in which red, blue, green and yellow panes were brought out after an exposure of many hours to sunlight; a group of colored draperies, which was successfully photographed in ten minutes by electric light, with a many-colored parrot and other objects taken with shorter exposures. Green foliage and gray stones came out well, but the sky had an in-

aligo hue. By the Lippman process the colors are all taken in one picture, the method consisting in exposing a transparent plate with its film side resting on a reflecting surface of mercury, the interference of the incident and reflected light dividing the film acted upon into layers corresponding in distance apart with the wavelength of the incident light, and reproducing by reflection the color which produced the layers.

It is, perhaps, not generally known that petroleum can now be produced artificially by a very cheap and simple method, being the distillation, in a strong iron vessel, under a pressure of 25 atmospheres, of the animal fats and oils at a temperature of 300° to 400° C. Under favorable conditions 70 per cent of the fatty oil is transformed into petroleum, which is 90 per cent of the theoretical yield. The product thus obtained has been found to be in every particular identical with natural petroleum. It is suggested that, with modifications of conditions in the process, oils of different grades may be produced.

M. F. WALTER has found that an alloy consisting of ninety-five parts of tin and five parts of copper adheres so tenaciously to glass that it may be employed as a solder to join the ends of glass tubes. It is obtained by adding the copper to the tin previously melted, agitating with a wooden stirrer, casting or granulating, and then remelting. It melts at about 360° C. By adding from one-half to one per cent of lead or zinc the alloy may be rendered either softer or harder or more or less easily fusible. It may also be used for silvering metals or metallic thread.—Revue Scientifique.

ELECTRIC CURRENTS in plants are due, says Kunkel, to the movements of water in the tissues, and not to differences of potential, existing independently. It was considered probable that vegetable electricity was due to biological processes, especially respiration and the consequent chemical changes. In experimenting with leaves and flowers dicotyledons and on a large mushroom in an atmosphere of hydrogen, it was found that the electric current was diminished, but never quite suppressed, owing, probably, to intramolecular respiration. The electric current revives on air being readmitted.

In a new primary battery devised by Mr. H. C. W. Emery the cells are formed in the shape of a ship's rudder, the elements being suspended vertically from the mouth, which, as compared with the lower part of the cell, is of small area. The elements consist of zincs and carbons, and when the battery is in its normal position they are immersed in the electrolyte, which is a solution of chromic acid. The battery is laid on its front, so as to bring the cells and the elements into a horizontal position, when it is required to stop its action.

M. MAX SCHULER is said to have discovered, in the joints of persons attacked with chronic articular rheumatism, bacteria, which are always identical in like cases. These bacilli are short and thick, having at each end bright grains which aniline colors make still more evident. The discoverer has been able to cultivate these bacteria in bouillon, or gelatine, or on a piece of potato. Their culture requires a temperature of at least 25 degrees, and darkness is indispensable. When shall we have anti-rheumatic vaccination?

THE measurement of the illuminating power of arc lamps by ordinary means, with any approximation to accuracy, has long been recognized as a practical impossibility. It is now proposed that a 2000-candle power arc lamp shall be understood to be one requiring an average consumption of energy of 450 watts, the measurement being made at lamp terminals, and with an appreciable resistance in circuit with the arc. It is to be

hoped that the definition will be accepted, and this much-vexed question finally disposed of.

THE internal temperatures of trees has been investigated in Belgium by N. W. Prinz, who finds that, as a rule, a large tree is warmer than the air in winter, and a little colder than the air in summer. The mean annual temperature of a tree is practically the same as that of the surrounding air, but the monthly means differ by several degrees.

A POWERFUL LIGHT has been invented by Herr Ludwig of Bremen, produced by evaporating and gasifying petroleum. The light is white and has a candle power of from 3500 to 12,000, with an hourly consumption of less than a quart of oil to each thousand candle power.

SUCH has been the growth of popular opinion in favor of the sudden disposition of the dead by heat that there are now in the country 18 incorporated cremation societies, and during the past ten years about 3000 cremations have taken place.

THE most profitable street railway in the world, says the *Electrical Review*, is the Broadway cable in New York, which is now said to be earning 50 cents per car-mile, the biggest record ever made by a street railway company.

THE scales used in the London Mint can show a difference in the weight of a card after a name has been written upon it.

WITH the aid of platinum wire, a battery and an electric bell, one can hear a plant grow.

PIONEER REDUCTION CO., NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract, or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ores or concentrates.

Mechanical Progress.

A Lost Art Found.

A Des Moines, Iowa, man claims to have discovered the lost art of making what is known as Damascus steel. In proof of his assertion he is now making specimens of his new steel products, and has submitted them to eminent scientists, who have not been stinted in their declarations of favor and wonder. The new steel can be made at one-half the cost of modern steel. In addition to that, it has the quality which the best steel now made has. It tempers two points higher than ordinary steel and within two points of the diamond. It contains no carbon, requires no rolling, the finished product may be molded instead of hammered, and its tempering possesses the quality of springiness. He takes common refined wrought iron and fuses it in a crucible, and adds his chemicals, the secret of whose combination constitutes his discovery. He pours the molten metal into the mold of the sword blade, knife blade, or whatever he may desire to produce. It cools, it is tempered, it is polished and the article is finished. The process takes about an hour. The product is harder than any steel ever made; it may be bent without breaking; it has no carbon in it, and when the chemists examine it their analysis shows nothing but wrought iron. The manufacture of the finished steel articles, as they are made now, takes sometimes a month. He has applied his combination of chemicals to the manufacture of bronze. He makes the hardest bronze ever manufactured. He has not patented the idea, and will not, but when he shows to the world a sword blade that bends double, and then springs to its original straightness, that will cut a feather pillow or a bar of steel or iron, and yet whose analysis shows nothing but wrought iron, though it is four-fifths as hard as a diamond, he believes the world will appreciate the fact that he has discovered Damascus steel.

An Automatic Electrical Horse-Feeding Appliance.

An electric horse-feeder is a new invention for securing the regular feeding of horses during the absence from any cause of the stableman. The apparatus is very simple, the law of gravitation being depended upon to accomplish most of the work. The first requisite is an alarm clock, which should be good enough not to stop casually, but need not be expensive. The electrical plant is that needed for an ordinary electric bell, four cells of the Lelanche type of battery being sufficient for any distance up to 200 yards. The third portion of the apparatus is the feeder—that is to say, the vessel holding the grain. The clock, which is the prime mover of the whole concern, may be in the house, the harness room or anywhere, but if it be more than 200 yards away from the feeder a more powerful battery will be required.

To use the feeder, the first thing is to set the alarm of the clock at the hour at which it is desired that the horse should be fed. The food is then placed in a tin-like biscuit box, which is turned upside down and placed in the proper compartment of the shoot, when the lid of the box is drawn out; the grain then resting upon the floor of a trap-like arrangement, held in its place by a simple contrivance. When the alarm goes off a button is pressed, and the circuit is completed. A weight falls, the bottom of the feed box is released and the grain falls out into the manger.

Speedy Engines.

For the past several years English and American locomotive builders have experimented on high-speed track engines, and a machine of 90 miles an hour is the best they can turn out. A Frenchman has succeeded

in constructing an engine that by many tests shows a speed of 150 miles an hour. His engine does not turn the wheels, but works a dynamo, which generates a current, and this current is used to run a motor, and the motor is connected up to the wheels so that they can be revolved at any rate of speed desired, which steam in a cylinder cannot do. Of course the dynamo is located on the engine.

Firing Guns at Sea.

To one unaccustomed to the experience, it is anything but pleasant to be on board a line-of-battle ship at sea when the big guns are being fired. Before they are discharged the decks are cleared for action, and all the chairs in the cabin are laid down and tied together, while every bit of movable furniture is secured. The doctor goes round and makes sure that every man has had his ears stopped with cotton wool. The concussion when the charges are fired is tremendous, and the iron-clad quivers from stem to stern with the vibrations; in fact, the shock of the explosion is so great that every pane of glass in the skylights is invariably shattered, and much of the ornamental woodwork is splintered. After a few hours of this rough play the carpenters have a busy time in making things look presentable once more, for the ship resembles a wreck when she has finished her practice. Nobody likes it. The sailors standing by the big guns sometimes find themselves thrown all in a heap across the deck, and after an hour or two officers and men become as black as sweeps. It is impossible to be well out of the way of the annoyance, though perhaps the one place in the vessel where the guns trouble the crew the least is down in the engine-room, which is below the level of the deck upon which most of the armament is put.

The Largest Map in the World.

The giant of the map family is now in course of preparation and construction at Washington, D. C. It was begun over 12 years ago under the supervision of the United States Geological Survey Corps, and it will not be more than half completed at the end of the present century. Some idea of the gigantic plans upon which this map is being constructed and of the magnitude of such an undertaking may be formed by considering the fact that the portion which delineates the little State of Connecticut and the northern tip of Long Island is six feet in length and nearly five feet wide. When this wonderful map is finished, it will indicate the exact location of every brook, creek, river, hillock, mountain, valley, farm, village, schoolhouse and city in the land, and will show every public and private road and highway as perfectly as the surveyor's map gives them in the townships. When completed, this map will cover almost an acre in superficial area. This being the case, it cannot be either hung up or spread out, and in order to make the information it contains available, it will be issued on the sectional plan.—St. Louis Republic.

A Mile a Minute on the Sea.

A Welsh engineer has prepared designs for a vessel which he claims will attain a speed of 60 miles an hour. His proposed vessel is flat-bottomed, 550 feet long, 50 feet in width, wedge-shaped at each end for 100 feet of her length, with a displacement of some 14,600 tons. Such a vessel, fitted with 16 paddle wheels, driving at 170 revolutions a minute, this sanguine inventor believes would be propelled through the water at the rate of 60 miles an hour. This would be breaking the record with a vengeance, for the Lucania, which has just eclipsed all previous performances, averaged barely 22 miles an hour. The 16 paddle wheels of the proposed express passenger steamer would be placed eight on each side, one behind the other in a water channel running

fore and aft just above the ship's bottom. They are of a peculiar construction, the paddle always maintaining a perpendicular position, and always entering and leaving the water at exactly the same point.

Incandescent Lights.

The beautiful little glow lamp, with its fragile hulk and delicate filament, is a far more interesting production than its massive and cumbersome progenitor, the arc lamp. The process of manufacturing the carbon filaments from bamboo threads is a long and intricate one, and is carried on in strict seclusion as a trade secret. But we can see the quick-fingered girls pick up the hairlike filaments and joint them to the little pieces of platinum wire which are fused into the neck of the bulb; to the platinum wires are soldered other pieces of copper wire, which connect with the brass screw cap and nut, insulated from each other by plaster of Paris, that form the base of the lamp.

When the filament is inserted in the bulb and the base sealed up, the tube which projects from the top of the bulb is connected to a mercury air-pump to exhaust the air from the bulb; this done, the tube is cut off and the hulk sealed up at the same moment, leaving the little point or cone that is to be seen on the top of all incandescent lamps. There are many intermediate operations in the evolution of the glow lamp, and every part of the work is checked by the most careful supervision, and each lamp is closely examined and tested before being wrapped and packed for shipment. The carbon filaments must be accurately measured and their resistance tested, the platinum wires must be just so long—or, rather, just so short—and no longer; every joint and connection must be perfect, and every juncture of glass with metal must be rigorously airtight.

A PRINTING PRESS is now building for a New York paper which will print a sheet in black ink, as usual, upon one side, while upon the other it prints four colors, and will do this at the rate of 20,000 four-page papers per hour. It not only prints, but also inserts the pages together properly, pastes them in place, and counts the papers in bundles of any desired number.

San Francisco Pioneer Screen Works

JOHN W. QUICK, Proprietor.

IMPROVED FACILITIES, FINEST WORK, THE LOWEST PRICES.

Perforated Sheet Metals, Steel, Russia Iron, American Platin, Zinc, Copper and Brass Screens for all uses.

MINING SCREENS A SPECIALTY.

221 & 223 First St., San Francisco.

QUARTZ SCREENS

A specialty. Round, slot or burr slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American platinized Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

TUBBS CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Steel Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice. 611 & 613 Front St., San Francisco, Cal.

LIGHTNING LARGEST WELL MACHINERY Works.

All kinds of tools. Fortune for the driller by using our Adamantine process; can take a core. Perfected Economical Artesian Pumping Rises to work by Steam, Air, etc. Let us help you. THE AMERICAN WELL WORKS, Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

J. F. CROSETT, Commission Mining Agency.

623 Sacramento St., San Francisco, Cal. Buy and Sell Meritorious Mining Properties. I have orders for Income-Paying Mines at the present time. Have also some good properties for sale. I want more mines to offer to purchasers and also desire more purchasers to examine properties I have to offer. Correspondence solicited.

Founded by Mathew Carey, 1785.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, Jr.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdy, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dumps; duty of miners' licks, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

Electric Progress.

Railway-Track Construction.

The electric welding process which has for some time past been considered with reference to constructing railway lines with continuous unjointed tracks has been experimented upon from time to time on various tracks sufficient to point to the adoption of this method of construction in the future. There are many advantages to be gained by the use of a continuous unjointed rail from a mechanical point of view, and it is especially desirable for an electric railway on account of securing a continuous return circuit without the use of rail bonds.

Rail joints are the weakest part of a track system, and any number of devices have been tried to reduce the wear at these points; but with the most rigid construction the ends of the rails break down and wear out much sooner than any other part of the rail, and as soon as any wear takes place there the hammering of the wheels interferes very materially with the comfort of traveling and introduces a difficulty in attaining high speeds.

The former practice in track laying was to separate the ends of the rails at the joints an eighth of an inch or more. In this case the pounding of the wheels was so severe that the joints could be easily counted by a passenger riding on the train. As railway speeds increased, this space at the joints has been decreased and the connections at these points made as rigid as possible without experiencing any trouble from expansion.

The usual rail employed in electric street railway work is a deep girder pattern which is imbedded in the roadway, and which, therefore, should be less subject to variation in length from the extremes of temperature in summer and winter than the T rails on the steam roads, which are entirely exposed to the air.

The effect of temperature upon a continuous track has been experimented upon, and the results show that there is no motion of the track between wide ranges of temperature. The effects of expansion and contraction are confined to a slight tension or compression of the iron, which is shown by a very small variation in the section of a rail.

All practical considerations, therefore, favor the adoption of a continuous rail, and the only difficulty in the way of this method of track construction is in providing a suitable means of welding the joints without injury to the metal, and herein seems to lie the chief weakness of the system.

A considerable length of track has been welded in Boston on some of the electric lines in that city, and while no effect has been found to result from expansion, there have been about ten per cent of the joints broken in service, which must be attributed either to the tension on the rails due to contraction, or to the weakness of the joint due to the welding process. It is probable, however, that defects in the welds are accountable for the breaks, as this trouble has not occurred in tracks where the ends have been mechanically connected without any provision for contraction. The fact that the breaks occur also at the welded joints and not in any other part of the rail is very good evidence that the welds are not as strong as the body of the rail.

This subject is called to prominent attention at present by the announcement that a new Brooklyn electric railway company is preparing to install about 100 miles of track all of which is to be welded by the electric process. The method generally employed for this operation is to equip a car with the necessary converter, which is run from the trolley line, and the welding machine, the latter being placed in a convenient position for attaching to the rail joints as the car passes along the track. In welding a nine-inch girder rail, in which the section of the joint was about 25 square inches, the elec-

trical energy required was found to be about 150 kilowatts. The joint may be easily straightened with a hammer while the metal is still red hot.

The advantages of a continuous rail for electric railway work lie principally in the saving of labor and repairing that are necessary where rail bonds are used, and a small amount of supplementary wire in the ground circuit. There are comparatively few roads on which the bonding and connections of the return circuit have a conductivity equal to that of the rail, and this condition naturally introduces extra resistance in the return circuit.

The chief objection to welding tracks at present, therefore, is the difficulty of making the joint as strong as the rail, and if this can be overcome the method will find a very wide application.—Electricity.

Electric Riveting.

Electricity has come into play in about every branch of mechanics, and it is not surprising that riveting by electricity is a success and an important improvement in the industrial arts. The apparatus consists of a transformer, the primary of which is formed of a heavy copper bar laid parallel to a coil of fine wire, and over the two are clamped angular segments of iron, forming when united a completed iron shell, increasing by this arrangement the efficiency of conversion. The structure creates a current of great volume in the copper bar, and in the end of this bar are mounted an anvil (having a regulating screw for moving it up or down) and a follower provided with a screw. In the circuit of a primary is placed a choke coil provided with a regulating switch for cutting in more or less of the coil, by which the strength of the current induced in the secondary may be controlled. The bars or pieces of metal are placed upon the anvil and the rivet dropped in place, the handle being then screwed up until the plates of metal are firmly held between it and the two insulating legs secured to the upper limb of the copper bar. The face of the bar is covered with insulating material except at a central point where it is left bare; and when forced against the rivet, the latter establishes connection from the upper limb, or the primary bar, to the lower limb, the current developing sufficient heat to make an upsetting of the rivet shank very easy under the pressure of the screw.

The Forge Superseded.

George D. Burton of Boston, before the Franklin Institute of Philadelphia, recently, showed the method of heating by plunging the metal to be heated into a bucket of water and passing a strong current through it. The apparatus consisted simply of an ordinary wooden bucket containing a large sheet of lead which formed the positive pole and an iron bar laid across the bucket forming the negative pole. The metal to be heated was held in the tongs, which were rested on this iron cross-piece, and dipped into the liquid as desired, thus avoiding all flexible connections with the tongs. Two ordinary nails held in the tongs and dipped in the liquid were heated to a welding heat in a few seconds, after which they were welded on an anvil with a few blows of the hammer. In another experiment they were welded by simply allowing them to fuse together. A large soldering iron was heated red-hot in less than a minute. Pieces of clean steel were heated to redness to show that they were not burnt, as in the ordinary forge.

The solution which he found to be the best, after a long series of experiments, is made of a solution of ten parts of carbonate of soda and one of borax, dissolved in water until the specific gravity at 70° is 1.150. The current was taken from the street mains and at about 240 volts. It appears that no means of regulating the current were used, as the metal itself and the depth of immersion acted

as the regulator. He claims to have made the first public exhibition as early as October, 1890.

Electricity for Reporters.

A tiny electric light fastened to the end of a pencil is a recent invention to enable reporters to make notes in darkness, and to find the keyhole when they reach home. The latter feature of the invention is one which an experienced investigator says will be of use to every one except the man who stays down at the office so late balancing his books that on his arrival at his own door he sees double or treble. The sight of two or three illuminated keyholes would only complicate his difficulties and result in an immediate necessity for the erection of more insane asylums.

GREAT FALLS, MONT., is called the Electric City. A dam across the Missouri, at Black Eagle Falls, three miles above the town, furnishes the electric power for the street car line. Elevators, printing presses, cranes and all kinds of machinery are operated by it. Housewives cook and sew by it, merchants use it for various purposes and rock-crushers are operated by it.

By the device of an Italian seismologist, an earthquake shock is made to light an electric lamp for a quarter of a second, causing the face of a chronometer to be photographed, and thus registering the precise time.

THE use of electricity has made it necessary for sentries on British warships to discard side arms when on duty. The arms become, it is said, magnetized by the dynamos and affect the compasses.

NEARLY all the electrical inventions, excepting the lightning-rod and the telegraph, have come in use since the Centennial Exposition.

Practical Information.

The Telephone of the Future.

The fortunes made in the telephone business have in the past been very large. This is by reason of a monopoly closely holding an article of great convenience and selling it only to persons of more than average means. The great drop in the price will bring its use within the range of moderate means, and although hereafter millions cannot be made by any select few, the average will be very satisfactory to those interested in the further development of the industry.

We are not given to fortune-telling, but we believe that within the next year there will be too lines for private use where there is now one. In the way of small exchanges there will be many installed during the coming summer. At the moment New York dealers have several orders for these on their hooks. In country districts neighbor will co-operate with neighbor, and the whole will terminate at the village postoffice or the country store. Many a trip will be saved in going after a letter that "has not come," and many a little errand performed by a passer-by whose intention of "coming this way" is known in advance.

Then in more populous districts the butcher, grocer and purveyor of the necessities of life will establish short "way" wires to favored customers, and get orders in that manner. The staples will in large numbers be connected with the house, neighbor with neighbor, druggist with physician, restaurant with apartments, and so on indefinitely.

What Makes the Sky Blue?

If there was no dust haze above us the sky would be black. That is, we would be looking into the blackness of a limitless space. When in fine, clear weather we

have a deep, rich blue above us it is caused by a haze. The particles in the haze of the heavens correspond with those of the tube in the konescope and the blue color is caused by the light shining through a depth of fine haze.—Science.

For Sudden Toothaches.

Toothache is a little thing in the books, but many physicians would rather meet a burglar at the door on a dark night than a call to cure a bad toothache of several days' continuance. A hypodermic of morphine only postpones the evil day, and usually the patient is respectfully referred to the dentist. The tooth should not be extracted while the jaws and gums are inflamed and the latter swollen, and it is the physician's duty to treat the case until the above conditions are removed. Always keep a small vial containing the following mixture: Chloroform, gtt. x.; glycerine, gtt. x.; sat. sol. ac. carbol., gtt. x.; morphine, gr. j., with a small wad of absorbent cotton. If the offending tooth has a cavity or decayed surface saturate a small pellet of cotton with the above mixture and put into the cavity or against the decayed surface, as the case may be. Never pack the cotton in or the more is the trouble, but have the pellet small enough to enter without crowding. In most cases this will end the trouble.

When the gums are swollen and tender paint two or three times two minutes apart with a 4 per cent solution of cocaine. This time of year your patient may have been eating a good deal of fruit. The tongue and mucous membrane of the mouth are pale, he has a sour stomach, and next day the toothache will return. Give ten grains of subcarbonate of bismuth and ten grains of phenacetin at once and a smaller dose before each of the three following meals, with a laxative if needed, and stop all fruit for a few days and it will not return. The same powder every two hours, with cessation of fruit-eating, will stop the persistent, tormenting neuralgias so prevalent at this season.—Medical Record.

A Telephonic Bullet Probe.

Those who followed the story of Garfield's last days closely remember with what difficulty the location of the fatal bullet in the dying President's body was discovered. Ordinarily a surgeon probes such a wound with a blunt-pointed, slender and pliable thread of metal, which follows the thread of the projectile more or less easily, and he detects the presence of the ball for which he is hunting by the resistance, and the kind of resistance, it offers to further progress. But even the most delicate sense of touch and the deftest manipulation are often baffled in a search of this kind, and various attempts have been made to use electricity therein. One of the most successful devices for that purpose, invented by Dr. John H. Gardner, of New York, is described by the *Western Electrician*. From a telephone receiver, fitted to the operator's ear, two wires extend, one terminating in a metal bulb, which is placed in the patient's mouth, and the other in a probe. When the latter comes in contact with the bullet, though the operator may not perceive the fact by mere feeling, a distinct rasping sound will be audible in the receiver. Up to that moment nothing is heard. The telephonic probe has been officially adopted, it is said, in the United States army and navy, and in the German army.

Simple Cure for Hiccoughs.

"I was just about to send a cure for hiccoughs to a New York man whose case has been puzzling the doctors, when I read that he had been cured by laughing heartily. All you have to do is to lie down, stretch your head back as far as possible, open your mouth widely, then hold two fingers above the head, well back, so that you have to

strain to see them, gaze intently upon them and take long, full breaths. In a short time you will be entirely relieved of the troublesome hiccoughs.

"Now, I have tried that snre cure on all sorts of cases, from the simple form to the chronic, and it works well with all. I remember it was given to a man on the way to New York to consult a specialist on his case—one of six months' standing—and it cured him in a few minutes. He turned around and said: 'What do you charge for that?' 'Nothing,' was the reply, 'except that you publish it to snfferers.'"—Pittsburg Physician.

Conversational Sounds Among Ants.

It has been suspected that ants communicate with each other by sounds that the human ear cannot perceive. A French observer, M. C. Janet, has now succeeded in making some of their sounds audible, showing that certain species of ants—notably *Myrmica rubra* L. and *Tetramorium caespitum* L.—are in the habit of making a stridulating noise, probably by rubbing together rough parts of the body's surface. The demonstration is simple. A circle of putty is formed on a pane of glass, the ants are dropped into the center, and a glass cover is placed on the ring and pressed down until the ants have just room enough to move about freely. Suitable air holes enable the prisoners to live in this place several days. When the glass box is held to the ear a faint murmur like the gentle boiling of a liquid in a closed vessel can be heard and then distinct stridulations in the midst of the murmuring. These sounds can be distinguished only when the ants are disturbed.

CARL WINSLOW, in a Copenhagen publication, advances the theory that the so-called "canals" on Mars are scratches made by bodies coming into collision with that planet. When meteoric masses closely approach the earth, their friction with the atmosphere generates heat enough to burn most of them up; and the largest masses that ever survive this ordeal and come down to our level, rarely weigh over 100 pounds. Out just beyond Mars, though, lie the orbits of several hundred celestial bodies, called asteroids; and Herr Winslow fancies that these, and not meteors have done the work in question. Some astronomers have thought that possibly the moons of Mars are captured asteroids.

THE extreme age of the various species of trees is set down as follows: Elm, 335; pine, 450; chestnut, 600; olive, 700; the cedar, 800; the oak, 1500; the yew, 2800. Humboldt computed the age of the famous baobab tree, a species of banyan, to be at least 5700. Late authorities give the age of "big trees" in California to be 3000 years.

FROM a report on the production of coal in 1893, compiled by E. W. Parker of the United States Geological Survey, it appears that the total production for the year was 179,326,612 short tons, with a valuation of \$205,256,479.

THE gold yield of British Guiana in 1893, according to the returns of the Department of Mines, amounted to 142,633 ounces. Compared with the returns of 1892, there appears to be an increase in four districts, aggregating 23,262 ounces.

THE hottest place in the United States, according to the 1893 meteorological reports, is Bagdad, Arizona, where the mercury often stands as high as 140° in the shade for a week at a time.

A GERMAN officer has invented a motor in which a fine stream of coal dust is utilized to drive a piston by explosion, in the same manner as the gas in the gas engine.

BOOKS ON ASSAYING.

By C. H. AARON.
Part I.—Gold and Silver Ores.
SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:
Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.
The volume embraces 130 12mo. pages, with illustrations, well bound in cloth 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.
Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.
This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:
Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Oxy Luasac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.
One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Usefulness of Tank Steamers.

About all the molasses which comes from Cuba to the United States is brought in the same tanks in steamships that are used to carry petroleum as a return cargo. The ship's tanks are about 16 feet deep and have a neck seven feet deep. They are pumped full of oil at Brooklyn or Philadelphia, then taken to Havana, and the oil is pumped out into the tanks of the refining plants there. Molasses is brought from the interior of the island in huge hogsheads, which are emptied into the storage tanks. A suction pump drawing about ten thousand gallons an hour fills each ship's tanks to within about two feet of the top, that amount of space being required for the expansion of the molasses. It might be supposed that the petroleum would have a bad effect on the molasses, but it has been shown that the contrary is the case; and as nearly one-half the importation is made into rum and the balance refined into sugar, a little oil is not much account. The tanks are cleaned after the molasses has been pumped out by turning in a powerful steam jet, which washes down the sides and liquefies whatever molasses may be left in the bottom of the tank, and the suction pump finishes the work. A cargo of molasses, which formerly required ten or twelve days, can now be unloaded in 48 hours, while the difference in the cost of handling, to say nothing of the saving of time, amounts to a large sum.

The Gulf Stream.

One of the natural phenomena of the earth that has been the subject of almost endless discussion is the Gulf Stream. Various theories have been advanced to account for its origin, but few of them have stood the test of investigation. One very plausible theory is that through volcanic action the basin of the sea has at some time cracked or broken, and that through these fissures water has penetrated the volcanic strata. Intensely heated by the subterranean fires, it rises to the top of the ocean and moves according to the natural law of circulatory currents. The process is as simple as the circulation in the kitchen-range boiler. The water enters the heated locality at one point, becomes hot and rushes out at another. With the extremely high temperature of volcanic matter, it is not difficult to see that there must be tremendous pressure. If the water is confined, and that an enormous quantity may be held in some cavernous basin. The illustration is easily made by the idea of dropping a V-shaped passage into the earth. The low portion is filled with hot water that pours in at one arm or end and out at the other. Given a large passageway, a suitable basin and a fairly active volcano, and a well-developed gulf stream becomes the simplest and most natural thing in the world.

The Torch Fish.

A deep-sea curiosity is the torch fish. This strange creature, with triangular jaws filled with long, slender teeth, a cartridge-shaped tongue and a body not unlike a dilapidated old shoe in shape, has upon the tip of its nose a slender stem bearing an egg-shaped object that may be illuminated at the owner's pleasure, and put out when he so pleases. The lantern does not serve as a guide to its wanderings, but is used as a trap to entice unwary and innocent food fishes. When *Linophyrus Lucifer* is hungry he lights his lamp, which is merely a phosphorescent lip to the egg-shaped body, opens his mouth, and waves before it a slender, cord-like appendage that grows beneath the lower jaw. The small fishes mistake the light for a phosphorescent insect and, in their scramble for this dainty, they fall into the capacious mouth that stands open to receive them. When he has dined to his satisfaction, he turns off the light, and goes about his business.

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents of the Denver Fire Clay Co., and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$6.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formula as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

PARAFFINE PAINT CO.,

116 BATTERY STREET, SAN FRANCISCO.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the slides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

Adamantine Shoes and Dies

—AND— CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill supplies.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Calaveras.

A FAMOUS MINE.—Stockton Independent: The famous Gwin mine of Calaveras county, a gold-producing property which has a record of having paid the owners something above \$2,000,000 in dividends, is soon to be reopened by capitalists who are confident of restoring the mine to its place among the leaders of the State. The mine is located on the Mokelumne river, about 60 miles from Valley Spring. The property is now in the hands of a corporation formed to work it, and is held under a contract of purchase which gives the company two years to pay for the mine. The purchase price is \$300,000, and the deed is in escrow. The president of the corporation is M. W. Belshaw, the owner of coal mines near Antioch, and the vice-president is Senator F. C. Voorhies of Amador county. It is planned to sink a three-compartment shaft on the vein, starting at a point 350 feet distant from the old works and going to a depth of 3000 feet if it is found necessary. The old vertical shaft was at a depth of 1500 feet when operations were stopped. The old works were extended a distance of 1000 feet along the vein, and there they stopped because the end of the company's ground had been reached. After closing down the company bought an extension of 4000 feet, and this is the ground which will be cut into. The vein runs from 13 to 30 feet in width and the rock averaged \$7.50 in free gold and \$1 in sulphureta to the ton. When work was stopped the vein in the face of the drift was 13 feet wide, and the ore was of excellent quality.

Inyo.

RED ROCK A FRAUD.—Inyo Register: From the report given by Henry McDonald, who returned from Red Rock and Goler a few days ago, it is fair to pronounce that a splendid section to stay away from. He says nothing is done in the way of finding gold, and few, if any are making wages, or anywhere near it. The owners of some of what have been reported to be the best mines in the section, "paying \$20 a day per man," are unable to meet even the smallest obligations. Apparently the agitation is kept up by some who have claims to sell, or have other reasons. McDonald says that the Mexican mine, reported to pay from \$100 to \$1000 a day, was sold for \$300 lately. Hundreds of men have come in there, worked hard to find something paying, and left "cussing the country." Consequently it seems that the best possible advice concerning Goler is to stay away from there.

Nevada.

A GOOD CLEAN UP.—Telegraph: Yesterday the Wisconsin mine had a clean up and the 55 loads yielded at the rate of \$40 per load. A short time ago a crushing of 50 loads, or thereabouts, yielded the plucky workers \$78 per load, and later a crushing of 60 loads paid \$70 per load. The Wisconsin is looking well, having a good ledge in the shaft and in the drifts. The young gentlemen who are working the mine are energetic and enterprising.

A BOOMING TOWN.—Grass Valley Union: The Allison Ranch, when started up, will give employment to between 200 and 300 men. This means that about \$1000 more per day will be placed in circulation in this city than at present, or about \$30,000 per month.

DEADMAN'S FLAT.—Tidings: At the Evening Star mine the water has not yet been pumped out of the lower levels. The new shaft is now down 40 feet.

At the Normandy sinking is continued and the shaft is down 75 feet.

The Picayune gravel claim is being worked by Mr. Torpie, Chas. Cross and the Grant Bros., who have done a great deal of dead work and have just got into the gravel, which will yield about \$10 to the car.

REOPENING THE MERRIFIELD.—On Monday morning work was commenced on the new hoisting works at the Merrifield mine, says the Nevada City Herald. The incline is down over 60 feet, and a hoisting rig will be put on as soon as the building is ready for it. In the course of a few weeks there may be employment there for a few men, as the company are pushing the job with their accustomed vigor.

WILLOW VALLEY.—Herald: There is considerable activity in Willow Valley this spring. Willow Valley has long been known as a good quartz district.

In the Buckeye claim the tunnel is in porphyry, easy to work, and there is a ledge in sight which runs from 18 inches to 5 feet in thickness.

Garner, Jones & Co. are again working the Montana, which has lain idle for several years. Their incline is down 400 feet and full of water. A steam engine has been set up and an eight-inch pump put in, and pumping was commenced to-day.

On the south side of the creek men are prospecting the Murchie, and water power will be put in for hoisting and more men put on in a short time.

OSBORN HILL.—Telegraph: J. B. White is laying off the mill site for the mill at the Osborn Hill mine. The mill will be a 20-stamp one and will be equipped with all modern appliances.

STRIKE IN THE HOME.—Transcript: A strike was made at the Home mine lately which is considered by mining men as one of the most important that has been made in that locality for many years. In the 200-foot crosscut from the shaft a fine ledge of rich quartz was struck, the ore from which shows well in free gold and is heavily charged with high-grade sulphurets.

It is believed that the old original Home ledge has been struck. When worked years ago it was very rich, but for some reason operations were suspended. About a year ago the present company took hold of the mine and erected a hoisting and pumping plant.

Charles Stepp of San Francisco, president of the Home Mining Company, is at present in Nevada City, and feels highly elated over the developments made at the mine.

The mine is situated only a short distance below the Providence, and this strike has an important bearing on the latter mine, inasmuch as it shows more than ever the existence of rich quartz veins in the hill into which the locations of both the Home and Providence companies extend.

MINING NOTES.—Transcript: The Buckeye quartz ledge in Willow Valley district, which is owned by T. B. Gray, is now being opened up by Luke Voice, who is running a tunnel. The ledge runs all the way from eighteen inches to five feet.

The old Montana mine, on which no work has been done for a number of years, is to be worked again. A steam engine and eight-inch pump have been put in place and recently pumping was commenced to get the water out of the 400-foot incline, which is nearly full. Garner, Jones & Co. are the owners.

Three men are prospecting the Murchie mine at a point near the south bank of Deer creek. Water power is to be put in for hoisting, and as soon as this is done, more miners will be employed.

The German mine in Washington district may soon have a new superintendent. John Berra and a company of San Francisco men are talking of purchasing the mine; or if they do not take the German, will in all probability buy or bond some other mine in that district.

The Midnight quartz mine, located on Deer creek a short distance below the suspension bridge, will be worked this season after being idle the past two years or more.

Siskiyou.

MINING OPERATIONS.—Yreka Journal: Hall & Fitch, who purchased the Finley Tribe mine at Salmon river, have a large force of men at work, with plenty of water to keep the giants in constant operation. The cleanup last month of 30 days amounted to \$10,000, and the regular daily yield is not less than \$200, some days more. They are also building a new ditch higher up on White's gulch, so as to have a still better supply of water for running all summer.

The rich find at Horse creek, a tributary of Klamath river, near Oak Bar, has created some excitement, and the country in the vicinity is full of prospectors, who have been staking out numerous claims. No doubt there are some good quartz mines in that section and throughout all the foothills of the Siskiyou and Coast range along the west side of Klamath river, throughout the entire length of Siskiyou county, from near the Oregon line on the north to the extreme corner on the south, adjoining Humboldt and Trinity counties.

Good placer diggings have been discovered at Elliott Creek, on Siskiyou mountain, just this side of the Oregon line, which will be a lively camp this season. Fred Kohls of Oak Bar, J. J. Walters of Klamath river, and others, have located claims. Fred Kohls allowed a couple of men to do assessment work and receive all they made, which has amounted to \$100 a week. There is considerable snow in the vicinity, but not very much where the sluicing down of the banks is carried on.

Wiley Parker and son, who have been ground sluicing at Portuguese Gulch, on Yreka Flats, cleaned up \$500 a few days ago. Owing to the great amount of water at bedrock, they have been unable to get down any deeper at present, and are working the quartz ledge in same claim until later in the season.

The Cherry Creek Mining Co., or Frank Riley and Henry Nixon, have been moving a vast amount of aniferous bank at Cherry Creek, and expect to do well when a cleanup is made. They have two ditches conveying the snow water from the summit of Deadwood mountain to a reservoir, rigged with a self-shooter in sending down when full a great body of water into the gravel sluices. Coarse gold is noticed in washing, and some small nuggets are picked up occasionally.

NEVADA.

Washoe District.

Regarding the Con. Cal. & Va. the Enterprise says that the crosscut 14 feet below the 1650 level, which had cut through 7½ feet of high-grade ore, had been pushed ahead through a narrow streak of low grade, and is again showing fine ore in the face. The advance of this crosscut has demonstrated the probability of the development of an extensive ore body of more importance than any discovery made in the mine subsequent to that of the bonanza 20 years ago.

The Alta mill is now dropping its stamps on ore from the mine, and should the vein in the vicinity of the 725 level continue and improve as rapidly as it has during the past ten days, the mill will be kept in constant operation.

A streak of ore four inches in width was cut through from the lateral drift from the intermediate tunnel in the upper workings of the Sierra Nevada, on Cedar Hill. This ore assays from \$20 to \$30 per ton in gold. The ground now being explored is in a region which has produced a large amount of gold hulsion from the surface workings, and a far more important development is among the probabilities. A shift of six men has been put on in the Crown Point. A night shift has already been put on in the Belcher. It is said that a night shift will be added to the force in the Yellow Jacket before the close of the week.

The Chronicle says: The place of the new find on the 1650 level of the Con. Virginia mine was visited by Superintendents Lyman, Sharon,

Gorman and Keating and Civil Engineer Haist. Messrs. Sharon and Gorman were afterward interviewed as to the appearance of the ore body. Both gentlemen expressed themselves favorably concerning it. Mr. Sharon said that the workings are looking fine and that everything indicates the presence of a big body of ore in the neighborhood. A drift will be run to strike the ore 30 feet below the 1650, and every indication favors the likelihood of striking it at that point. If such proves the case, the presence of an ore body of magnitude will be proved. The prospect is the next best thing to a certainty.

It was reported that the Con. Virginia ore on the 1650 level is to be tapped at two other points, 50 feet above and 50 below the present workings. For that purpose a south drift is being run, according to hearsay, from a raise, 50 feet up, in the direction of the ore. A west crosscut on the 1700 level, which was stopped in the neighborhood of the ore a couple of years ago, has also been cleaned out and is now being continued west toward the point where the ore is expected to come down from the 1650 level.

People who are acquainted with the country in question are confident that both workings will tap the ore. In case this happens, a very strong effect upon the market may be expected.

The workings from the Rule drift are reported to be looking better all the time, and a body of ore may be discovered there at any time.

Regarding the Con. Cal. & Virginia, the Enterprise further says in relation to the showing in that mine: "Colonel S. T. Curtis and Colonel E. D. Boyle were included in a party of experts who inspected the new ore development on the 1650 level of Consolidated California & Virginia mine yesterday. Colonel Curtis took numerous samples from the face and side of the drift on the 1650 level and from that 14 feet below.

"The ore is heavily impregnated with black sulphurets and is precisely the same character as that found in the bonanza of 1874. Colonel Curtis says that every feature of the new discovery indicates that it will make into an extensive body of high-grade ore. He says it lies to the west of a wide belt of low-grade ore, which had never been prospected heretofore, and he is of the opinion that it will show still stronger at a greater depth.

"He stated that the new ground in which the discovery is located is of ample area to include within its boundaries an ore body of a value only exceeded by the development in the mine of 1874. 'They have nearly 400 feet of ground between the 1650 and water levels, and I will be disappointed if this discovery does not prove to be fully as important as that of 1886,' said the Colonel.

"There is a large area of new ground to the north, west and south of the present workings, and this discovery is only the forerunner of a more important development.

"Colonel Boyle corroborated the statement of Colonel Curtis in every detail, and is even more deeply impressed with the importance of the new discovery. A practical miner, who was included in the party of inspection, and whose judgment is relied upon as being infallible, coincided with the opinions of Colonels Curtis and Boyle.

"It was later learned that Superintendent Kinkead was included in the party of experts. Mr. Kinkead says there is about 18 feet of ore now exposed in the drift 14 feet below the 1650 level, and that the crosscut to be run 28 feet below the 1650 level is sure to cut the downward continuation of the ore body, which it will reach in about ten days. He says the outlook for the development of a large body is very promising, and that it is a long distance west of the old slopes and in entirely new ground, and therefore there is no possibility of encountering either old timbers or an inflow of gas."

Still later that paper says: From authentic and reliable sources it is ascertained that the rumor prevalent yesterday throughout the day to the effect that an important strike had been made in the Rule drift was without foundation. Work is steadily progressing, with bright prospects; rock giving low assays.

At the annual meeting of the stockholders of the Justice Mining Company, 93,245 shares were represented, and the following officers elected for the ensuing year: Aug. Waterman, president; H. Zedig, vice-president; and P. Amiraux, E. P. Barrett and S. Jacobs, directors. R. E. Kelly was re-elected secretary, and R. P. Keating superintendent. The superintendent's report showed the mine to be in a good condition. A grade of ore is being extracted which runs three-quarters in gold and one-quarter in silver. A test run of about 250 tons of ore which has been extracted from the various openings at present is being made at the Taylor mill and with very satisfactory results.

In the Occidental they continue to extract about eight tons of ore per week, of an average of \$41 per ton. During April 110 tons and slimes produced hulsion valued at \$1384.

In the Kentucky the south drift from the east crosscut on the 1035 level is in 16 feet; the face is in ore of fair quality. On the 1200 level the south drift from the Jacket incline is in a total distance of 69 feet; face in low-grade gold ore.

Nevada mining assessments falling due in May aggregate \$77,500.

Osceola District.

OSCEOLA HYDRAULIC DIGGINGS.—Enterprise: Hydraulic mining has started up at the Osceola in eastern Nevada on a grand scale. The Osceola gravel deposit is the largest and richest in the State—the largest in all the Great Basin region. The Osceola placers are nugget producers. Already many fine nuggets have been found—the largest weighing 24 pounds—and hardly a beginning has been made on the gravel deposit. This season they will have an almost unlimited supply of water, and we may look for fine re-

sults. The placer is of local origin, and it is known that the gold comes from the quartz veins above, on the slope of Jeff Davis peak. Little has been done with any of these veins. In the process of washing with the hydraulic other rich veins may be uncovered. No doubt the vein which is the producer of the big nuggets will eventually be found. As the gravel yields a paying amount of fine gold, the nuggets found from time to time come in as clear gain—a little golden godsend.

When the company shall have worked out their gravel deposit they may find good use for their water supply in driving water mills for the reduction of their quartz veins. Doubtless more gold remains in these than is found strewn below in the gravel that has resulted from the disintegration of the croppings. It is a region of great—of golden possibilities.

In the vicinity of Osceola are dry washings that are paying big wages. There is a great gold range running from the Osceola, down through the country toward Ferguson district. It is a good region in which to prospect. In such a belt the chances for finding paying parallel veins are always good. About Ferguson are also rich gold veins, and doubtless others of value remain to be discovered. Indeed, a gold belt seems to extend more or less regularly all down through the eastern borders of Nevada to the Colorado river. This region is attracting many Utah, Colorado and Montana mining men. Big prices are being paid for some recently-discovered mines.

Soda Springs District.

SODA SPRINGS DISTRICT.—Reno Gazette: So far eleven gold-bearing mines have been discovered in Soda Springs district, Esmeralda county, on the line of the Carson & Colorado Railroad, 50 miles south of Hawthorne. One ledge five feet wide has been uncovered that shows plenty of \$200 rock; another, four feet wide, shows up a big body of \$40 ore; and still another five-foot ledge that assays \$70 per ton. What is termed as the "waste rock" assays \$20 per ton. The district as a whole will average anywhere from \$20 to \$70 per ton.

Ferguson District.

PROSPECTING FOR WATER.—Pioche Record: Prospecting for water with a 1000-foot drill is one of the things that Captain J. R. de Lamar will undertake at Ferguson as soon as machinery for that purpose can be shipped in. This method has been successfully followed in a number of cases around Denver, Col. If a subterranean water channel can be located by this means—and there is reason to believe it may—the water question, and with it a good part of Ferguson district's future with regard to a disposition of its ores, will be settled.

ARIZONA.

Prescott Courier: James Howey and Peter Marx returned yesterday from A. W. Callen's Placita camp, where Mr. Howey has been testing a dry washer of his own invention, and found the same to work more successfully than anticipated. He brought in a vial of very nice-looking gold dust, the result of the experiment. He found that one man at the crank would keep another man fully occupied feeding screened dirt in the machine. The ground tested belongs to A. W. Callen and is being worked by Mexicans, who pack the dirt a mile to water and pan it out. One Mexican recently obtained an ounce of gold from a sack of dirt, while another Mexican a short time before that got from the same ground a \$50 gold nugget, which he sold at the Congress. Prospects can be found in every pan of dirt taken from this ground.

The sale of the Bullard mine is reported, the price being \$400,000. This mine is situated about ten miles south of the Santa Maria mines, being in the same mineral belt. There is said to be several million dollars' worth of ore in sight in this mine.

The richest gold mine ever struck in Yuma county was found last week, two miles south of the Monitor placer mines near Gila City. The vein is situated in the rugged range of mountains known as the Gila range, clear up in the summit in a canyon 60 feet deep, which the vein crosses. On the summit the vein is eight feet wide; in the bottom of the canyon, 600 feet below, it is 20 feet wide. The whole body of the ore prospects rich, while portions of it show very fine specimens of free gold.

BRITISH COLUMBIA.

More than 1200 claims have been located in the Slocan mining district since its discovery.

The Grant-Omaha Smelting Company will erect reduction works in the Kootenai. The site is not known yet, but will likely be at Three Forks or Nakusp.

The forces on several of the leading Slocan properties have been increased recently, the owners having full confidence in the future.

Residents of the Kootenai district are agitating for the establishment of a mint in Canada, and also that the government will buy only Canadian silver when they want more white metal coin.

The Big Bend gold country, about 60 miles above Revelstoke, is attracting attention this spring. A townsite has been staked out, and it looks as though there would be quite an influx of prospectors in June.

IN LITIGATION.—Spokane Review: A controlling interest in the Noble Five group of mines in the Slocan country is being negotiated with an Eastern syndicate, the price being reported at \$300,000. The group is one of the richest in British Columbia, having already shipped 400 tons of ore, which, it is claimed, yielded 150 ounces of silver and 69 per cent lead per ton. There is 700 feet of tunnel in three divisions already on the property. The width of the vein varies from 2½ to 6 feet, although in one place it is much wider, as in an upraise 9 feet of solid ore were encountered. A two-fifths interest in the claims is in litigation.

tion. Dr. Hendryx and Captain Hayward claim an interest with William and John Hennessey, under a grub-stake contract. The trial will be held at Vancouver, June 1st.

IDAHO.

THE POORMAN MINE.—Idaho *Avalanche*: The company's mill started up for "business" last Saturday, after a successful trial run, and is now running steadily and satisfactorily. The mill is equipped with stamps, table plates and Frue vanners, and so far, after thorough tests and assays, it has been demonstrated that the loss in milling is but trifling—a very small percent. Heretofore the method used on the ores of this property, as well as on all the War Eagle mines, has been the amalgamating process, or a series of pans and settlers. The cost of milling under the old process is expensive and unsatisfactory, requiring a large expenditure for power, chemicals and quicksilver, and saving but about 60 per cent of the value. The cost of milling has always been from \$10 to \$12 per ton, where, under the concentrating plan, the cost is reduced to \$2 to \$5 per ton, and the loss is practically nothing. Ore is being hauled from the Oso ore house now, and a force of miners is at work in the stopes, taking out ore. The npraise connecting the Belle Peck and Oso tunnels will be pushed as fast as practicable. A large ore house will be erected at the mouth of the Belle Peck.

BOOM LOOKED FOR.—The Lewiston *Teller* says: This will be a great year for mining prospectors. Nearly every paper you pick up has an item concerning a new party fitting out for the search of placer or quartz mining. A Spokane daily of recent date tells of a party fitting out to go placer mining on Selmon river this season. Others are going on the same errand. There is no doubt that the bars of the Salmon will yield handsome returns to the miner who works them, and it would be no surprise if tales of fabulous wealth could be truthfully told about some locations before the season is over. There is plenty of gold in the bars along the Salmon river. Such is the assertion of all who have prospected there.

MONTANA.

A FIFTY THOUSAND DOLLAR SALE.—*Inter-Mountain*: H. L. Frank has just closed a deal with the Anaconda Mining Company for the sale of several mining interests, for which he received \$52,500 cash. He sold a one-eighth interest in the Nepa, one-half of the Clerk Fraction, one-fourth of the Alexander and all of the Parrot No. 5. Some time ago the McGinnleys sold their interest in the Alexander for \$22,000 and Shelly Tittle sold one-half of the Clark Fraction for \$8000.

ANACONDA.—*Standard*: The new converter at the lower works was started up last Saturday. The building, which is iron throughout, is 380 feet long by 125 feet wide and contains 24 converters, with a capacity of turning out every month no less than 10,000,000 pounds of copper. It is fitted with all the latest improvements, including such new features as electric traveling cranes, hydraulic cylinders for blowing engines, and, in fact, everything that goes to make the finest plant, installed with the very newest inventions and improvements, that has ever been built. The new institution will give employment to 120 men. In a year from now this one building will have probably turned out enough of the dark yellow metal to furnish every one in the United States with a copper kettle, besides filling innumerable kettles of residents of this city with the necessities of life.

OREGON.

THE PYX MINE.—At the Pyx mine, situated about 40 miles southwest of Baker City, the force is constructing the milling plant and expect to be able to complete the work inside of a month. The plant will be started up with five stamps, but five more will be added July 1st. There are between 200 and 300 tons of ore on the dump and its estimated value is placed at \$40 per ton. The Pyx is developed by two tunnels. The upper is in 650 feet, giving a depth of 50 feet. In the face of this tunnel is exposed a five-foot free-gold vein. The lower tunnel is 200 feet long and gives a depth of 90 feet.

GOLDEN EAGLE MINE.—The amalgam resulting from the test run of 85 tons of rock from the Golden Eagle mine, on Applegate, was refined at Ashland last week by G. W. Johnson, and produced a handsome gold brick, weighing 963 ounces, worth \$1603.95. The ore was taken from a prospect shaft sunk from the croppings of the ledge to a depth of about 30 feet, and was hauled about 14 miles to the mill of Anderson & Holyoke for crushing. The mine is one of the few in Oregon which has paid for opening and working from the top down, and gives every evidence of being permanent.

GRANT COUNTY.—*Long Creek Eagle*: During the past winter some little work has been quietly prosecuted in the quartz mines near Susanville. Mr. John Hughes has put in most of the winter extracting ore from his property, which he will treat in his arastre. Mr. G. S. L. Smith has been working a force of men most of the winter on his Princess lode. He has been extending the drifts from the old workings, prospecting new ground, and, we understand, with satisfactory success. The Centennial Mining Co. have been doing some prospecting work, under the direction of Messrs. Stevenson, Scott and Smith, on their Oregon lode, and extracting ore which they will practically test in their arastre. Messrs. Sloan and Haskell have begun the cleaning out of ditches preparatory to resuming operations on their well-equipped Elk Creek property.

NEW MEXICO.

COCHITI.—The new Cochiti mining camp, which is causing considerable excitement throughout New Mexico, is about 40 miles north of Albuquerque, and is in Bemalillo

county. Wallis is the nearest railroad station, which is 13 miles from Allerton, the largest town in the new camp, although there are several town sites laid off. Two or three have stores, restaurants and saloons. The mineral belt seems to be narrow, and the formation is porphyry or belongs to the porphyry family. The belt is both aniferous and argentiferous. The mountains, though steep, are not inaccessible. The camp is what is called by prospectors a blind camp, with a few exceptions where large quartz ledges crop out boldly, and in some cases stand 20 feet above the soil.

Most of the mineral-bearing rock in place seems to be either capped with trap rock or covered with slide rock.

The mountains are covered with splendid mining timber, plenty of it large enough for saw timber, and plenty of water in the main canyons.

The course of the mineral belt is very nearly north and south.

The most prominent mines yet opened are the Lone Star, which has a quartz ledge 27 feet wide. Assay returns show it to be a profitable smelting ore; it runs well in both gold and silver, as do several other quartz ledges.

The Iron King lode has a large quartz ledge and is an extension of the Lone Star. The Crown Point lode is another quartz ledge, which has just shipped a carload of ore milling \$100 per ton; one mile from the Crown Point another lead is located, known as the Washington mine, a quartz ledge from 20 to 30 feet wide which has pay ore in abundance. Still farther to the west is the Whale, also located on a quartz ledge 30 feet wide. To the northeast is the Man's Delusion lode, one of the largest quartz leads in camp, which is said to run well. The course of these leads is about north and south.

The ore of the camp is probably petzite, although that can only be determined by a chemical test, as the only thing that resembles ore in the quartz is a bluish cloud here and there.

SOUTH DAKOTA.

TO TEST THE PROCESS.—*Deadwood Pioneer*: Prof. Uhlenberg, assayer for the Homestake Mining Company, left for Denver recently to investigate the merits of the bromine process as improved by Prof. Englehardt. Mr. Uhlenberg will demonstrate the practicability of the process upon half a ton of Homestake concentrates which he will have shipped to the Englehardt mill.

UTAH.

THE IREX MINE SOLD.—The sale of the Irex mine in the Detroit district, twenty-five miles west of Deseret, is reported by the *Salt Lake Tribune*, the consideration being \$150,000. The mine is considered one of the valuable gold and copper properties in this district. The purchasers are the Copper Plant Company, and it is stated a smelter will be built. The Irex has 25,000 tons of ore in sight, which, judging from recent assays, will run at least \$26 to the ton in gold.

A BINOMAH TRANSFER.—*Salt Lake Tribune*: The final arrangements for the taking up of the bond on the Stewart mine at Bingham have been made, and the property is now in the hands of the Egan syndicate. The bond called for \$150,000. Of this amount \$110,000 has been paid and the remainder is due in one year. The property was originally owned by Salsburg & Gilmer, and was bonded by T. Egan, E. D. Egan and Jnd Bates, who are now the owners. The mine is one of the greatest gold mines in the country. The ore body is, in places, 200 feet wide, and there is estimated to be 700,000 tons of ore in sight. The ore is free gold, and averages about \$9.20 to the ton. There are five Huntington mills on the property, with a daily capacity of about 60 tons. The mill saves about 75 per cent of the gold in the ore. The mill has been in operation about six months, and over \$100,000 has been taken out in gold.

THE IREX SOLD.—*Tribune*: The sale of the Irex mine in the Detroit district, 25 miles west of Deseret, is reported, the consideration being \$150,000. The mine was owned by Allen G. Campbell, S. F. Mount and H. Holbrook, and is considered one of the most valuable gold and copper properties in the district. The purchasers are the Copper Plant Company, and it is stated on the best authority that arrangements are now being perfected for the erection of a smelter at that point. The Irex has 25,000 tons of ore in sight, which, judging from recent assays, will run at least \$26 to the ton in gold.

BINOMAH: SALE OF THE STEWART.—*Herald*: The sale of the Stewart mine at Bingham to the Bingham Mining Co. is perfected. The mine brought \$150,000. There seemed to be a chance that the deal would not go through, the recent negotiations looking to the sale of the property to an Eastern English syndicate for \$300,000 having been declared off. In explanation of the small amount for which the mine was sold, the statement is made that the bond and lease were executed when the property was undeveloped and before the successful method of treating the ores was discovered. The mine was not nearly so valuable then as now, and the former owners—the members of the Stewart Mining Co.—considered that he was receiving a fair price for the mine, which is now considered to be one of the most valuable in the Territory. It is turning out between \$10,000 and \$16,000 in gold bullion every month, and the amount of ore in sight is said to be something marvelous. The rock averages \$9.20 to the ton, and the present method of treatment is saving 95 per cent of the precious metal at a cost of about \$2 per ton.

—The first train passed over the new railway line between San Francisco and San Luis Obispo last Saturday. The newly completed road opens up some splendid country.

Coast Industrial Notes.

—The California-street Cable Company has paid a dividend of 50 cents per share.

—The Edison Light and Power Company will pay a dividend of 66 2/3 cents per share on the 15th.

—The Alaska Packers' Association has declared dividend No. 5 of 75 cents per share, payable to-day.

—The California Electric Light Company has declared a dividend of 15 cents per share, payable next Tuesday.

—Foreign-made bags that have been sent out of the United States with grain in them and have been returned must pay duty the second time. So decides the Collector of the Port.

—The men employed in the Le Roi mine, about 20 in number, struck recently for \$3.50 a day and nine hours' work. The mine is on Trail creek, British Columbia, and is owned in Spokane. The owners declined to accede to the demand.

—The woods crew of the Pacific Lumber Company at Scotia, Humboldt county, numberlog 60 men, have struck for an increase of wages, demanding the same pay that other institutions are paying. The matter has been arbitrated successfully.

—The April lumber exports from Humboldt county were about half a million feet in excess of those for the previous month, but were 3,000,000 feet less than those for the corresponding month of last year, and nearly 6,000,000 feet less than those for April, 1892.

—The British ship Somaui recently arrived from Hongkong with 2500 tons of coal brought originally from Tonquin to Hongkong at a cost of \$2 per ton. It cost about as much more to get it across the Pacific, and the duty was seventy-five cents per ton. San Francisco is long on coal just now, and \$1 a ton was what the lot sold at last Saturday.

—The Ideal Placer Mining Water and Power Co. of this city, which owns about 400 acres of gold-bearing gravel near Camanche, proposes to tap the Mokelumne at Italian Bar, sixteen miles above Wallace, and carry water in a six-foot pipe, tapering to a two-foot pipe at Lodi, the idea being to supply 20,000 inches of water for mining and irrigation purposes.

—L. C. Dillman of Spokane, Wash., has proposed to the Tacoma Chamber of Commerce that it have all the unemployed men now marching on to Washington taken to Tacoma, fitted out and set to work digging three irrigating canals across the State, the men employed to be fed and clothed and their expenses paid, and their wages paid in interest-bearing bonds, secured by land along the ditches.

—The Board of Directors of the Turlock, Cal., Irrigation District Company let the contract for the completion of the entire canal, including tunnels, headgates, drops, lateral canals, etc., on the 4th inst. to Doe, Hunt & Co. of San Francisco. This will open up 176,000 acres of land to irrigation between the Tuolumne and Merced rivers in Stanislaus and Merced counties. The mammoth rubble masonry dam near La Grange, which is the highest overflow dam in the world for diverting water, was completed last December.

—The use of a chemical battery in supplying the electric current in telegraphy has been the sole means of supply so long that it was deemed impracticable to substitute a more direct form; but F. P. Medina of this city, a native Californian, has devised a dynamo that distributes electro-motive force direct, dispensing with the customary cup battery. The machine is in position in the office of the Postal Telegraph Company on Market street and furnishes the current to a quadruplex and twelve Morse wires. The inventor calls it a "multipotential dynamo." It is the result of five years of study and experiment and if successful, as it appears to be, will revolutionize that part of the world's telegraphic service.

—A new idea in loading lumber has been recently put in successful operation on this coast. Where sawmills are located near open roadsteads, difficulty has been experienced in loading lumber. The wire system obviates all that. The vessel is anchored, and picks up a wire attached to a buoy cable, by another wire being fastened at the top of the cliff. The water end of that wire is picked up by a boat and put aboard, when the two wires are joined, the slack made taut, a "traveler" slung on and the lumber sent down in slings, swiftly and easily, from the mill to the vessel's deck. The Point Arena wire is 900 feet long. The plan is a great thing for the formerly isolated mills along the rocky coast.

Patents Issued to Pacific Coast Inventors.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

FOUNTAIN MARKING BRUSH.—R. G. Bailey of San Francisco, Cal. One-half assigned to J. F. Halloran and Alfred Holman. No. 519,223. Dated May 1, 1894. The object of this invention is to provide a marking brush with a fountain attachment by which a proper supply of marking fluid is conveyed to the brush, and a means by which the material is prevented from becoming clogged within the passages, and a means for attaching an ordinary brush and replacing the latter when necessary. It consists of a tubular shank or handle, with means by which it may be filled with the marking fluid. At the lower end is a brush-holder screw-threaded to fit upon the end of the handle, made conical and having a conical valve which closes against the inner part to prevent the escape of marking fluid when the device is not in use. This valve has a flattened blade which extends through the narrow passage in the valve seat, and the upper end or shank of the brush fits into the enlarged chamber below this opening, leaving a space on each side for the liquid to flow down into the brush. The whole of this part is encased with a conical covering which tapers down so that only the brush appears below it. When the device is to be used, the brush-holder is given a slight turn which unscrews it a little from the handle, and this raises the valve to allow the marking fluid to pass. At the same time the blade at the end of the valve, turning around in the passage, clears the latter from any sediment and leaves it free for the flow of the marking fluid.

POWER WHEEL.—A. Blenkowski. No. 519,226. May 1, 1894. The object of this invention is to provide a wheel having vanes or fans which are adapted to turn or feather at certain points in the revolution of the shaft, so that at one portion of the revolution the vanes are presented with their faces in the direction of revolution, and at another part with their edges in this direction. This device is applicable either to be used as a wind or water wheel to which power is applied to revolve it, or it may be used as a fan to produce a blast by applying power thereto. The rotating shaft has radial vanes projecting therefrom with journal pins upon which they are allowed to turn about their axes. Independent stationary segments are fixed upon opposite sides of the shaft and partially enclose the same. The ends of these segments approach each other toward a central point so as to impinge upon the hubs of the vanes and rotate the latter by frictional contact while the shaft turns to carry the vanes successively between these segments.

Market Reports.

The Markets.

SAN FRANCISCO, May 10, 1894.

Amid the flutterings in the silver market the fact appears manifest that it has reached its lowest figure, and that from now on it will steadily, if slowly, appreciate.

The foreign copper market continues languid, owing to the over supply, unaccompanied by active demand, which tends to depress home prices. Lead follows silver in its fluctuations. Quicksilver is higher, at \$36 per flask.

Last week's notable advance in the price of commercial-bar silver is ascribed to the demand in India, China and Japan. The determination of Germany and France to coin more silver tended to stiffen the market. The decline in the latter part of the week is accounted for by the reaction consequent upon the adjournment of the London Bimetallic League meeting without definite action.

During April 2391 flasks of quicksilver were received here; the receipts for April, 1893, and April, 1892, were 1467 and 1856, respectively. The receipts for the first four months of this year are 9703 flasks. The exports for the same time were as follows:

	Flasks.	Value.
New York.....	3,000	\$ 92,000
Hongkong.....	2,000	53,973
New Zealand.....	10	300
Central America.....	404	12,020
Mexico.....	1,435	42,488
British Columbia.....	38	1,219
Canada.....	200	5,306

Total.....	7,087	\$207,306
In 1893.....	7,385	298,291

Assistant United States Treasurer Jackson at San Francisco reports cash on hand April 30, 1894, as follows:

United States notes.....	\$23,207 00
Treasury notes 1890.....	12 965 00
National Bank notes.....	47,910 00

STAMP MILLS.

VULCAN WIRE ROPEWAY

for Conveying ORE, CORDWOOD, ETC.

SNYDER MINE, KENNETT, CAL.

In reply to inquiry as to how Tramway is doing, nm prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.

It will give us great pleasure to recommend your Ropeway and your Company as well to any persons who may be thinking of erecting Ropeways.

SAN ANDRES, DURANGO, MEXICO, March 20, 1894.

I desire by this letter to testify, that the Vulcan Wire Ropeway furnished to this company by your Works, and erected by your engineer, B. McIntire, is of the very best class, and has given us entire satisfaction since its installation.

ANTONIO H. PAREDES, Director S. A. de la S. M. Co.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for picking on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clack changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clack cannot be changed under water. The self-tightening and self-lubricating stuffing box and new bucket also saves expense of dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, California.

UNION GAS ENGINE CO.

Pioneer Manufacturers

OF GASOLINE ENGINES AND OWNERS OF TWENTY PATENTS ON SAME

Engines for Mining Purposes a Specialty.

WARNING! If you are in need of power for mining purposes investigate this engine and take no other. Many so-called gasoline engines are now on the market, which are direct infringements of our patents and it is our intention to bring suit against the various infringers. As the law holds the purchaser, as well as the manufacturer, we would advise parties who have already purchased other gasoline engines to obtain from the sellers of such engines a good and sufficient bond protecting themselves in case damages are obtained against them, as it is not the policy of this company to work a hardship on innocent parties, but the law makes no such provision.

Vertical Compound Engine.

Engineers and the public at the present time seem divided in their preferences between two types of engines—the slow speed and the high speed, in the various forms which have recently come so largely into use.

Since the beginning of the rivalry between the two classes of engines, there has been a recognized place for an engine which possesses some of the undisputed advantages of the high speed type, in the direction of rotation, floor space and regulation.

The recent advent of electrical dynamos, arranged to be placed directly on the engine shaft, has greatly emphasized the want above described, because of the great saving in cost of dynamos when higher rotative speeds are employed, and the desirability also of close regulation.

With increased rotative speed shorter stroke is permissible, and hence the vertical form of engine offers many advantages.

The engine built by the Ball & Wood Company, Elizabethport, New Jersey, herewith illustrated, has many favorable characteristics in economy, rotative speed, regulation, cut-off valve gear, small floor space, adaptation for driving direct-connected dynamos and desirability for mill work.

The governing mechanism of an engine must be of special interest to the student of valve gears. Beginning with a well-known form of shaft governor, the principles of which have attracted the attention and admiration of the ablest engineers of the day, the superb regulation thus obtained is made effective by transmitting the necessary motions to the cut-off valves through a special wrist-plate device, in which a compound motion is obtained, and the cut-off valves at all points of cut-off operate relatively to the main valves just as though the latter were standing still, thus preventing wire drawing of steam at any point of cut-off.

The location of the valves in the cylinder head, giving

as it does the shortest possible ports, permits of their being of ample capacity without an appreciable increase of clearance.

The peculiar motion of the cut-off valve utilizes these wide ports to the fullest possible extent, and the cut-off motion at every point from zero to three-quarter stroke is a rapid one, in fact as rapid as is obtained from the re

Recent Specimens Sent to the Mining Bureau.

At the State Mining Bureau there has recently been received a collection of matted iron crystals, each one hollow, found 200 feet below the surface in Cochise county, Arizona. Apparently the crystals were formed first, and then coated with iron by nature's slow and sub-

tle alchemy. From La Perouse, Australia, has come a six-sided sandstone column, unlike anything ever before seen in this State. A fine sample of mica comes from Kamloops, British Columbia, that is reported to be in quantities sufficient to make it merchantable. The New Almaden mercury mines also send some splendid cinabar specimens from a recently discovered lead in those famous mines, exceedingly rich in quicksilver. Several fine specimens of gold quartz from the White River District, Tulare county, have been sent in. It is not generally known that Wells-Fargo all over the coast will transport free of charge anything of a mineral character weighing twenty pounds or less to the Mining Bureau in this city.

THE prevalent impression is that the Midwinter Fair concessionaires have been having a hard time of it; but the official government figures tell a different story. The customs duties alone on goods sold at the Fair to the 1st

amount to over eighteen thousand dollars, showing that over \$100,000 worth was sold. There has also been a large amount sold on which duty had been paid at the Chicago Fair. Besides, large quantities of merchandise have been sold by sample. The facts are in opposition to the plaint of the exhibitors.

THE Oxe movement is being worked for all it is worth by sending undesirable citizens back from whence they came.

At the end of 1892 the proportion of gold to silver was 15½ to 1. At the present time it is 35 to 1.

NEW TYPE OF VERTICAL COMPOUND ENGINE.

leasing gear, because of the higher rotative speed of the engine.

THE extraction of Comstock ore through the Suto tunnel is again being discussed. That is what the tunnel was for, but the bulk of the bonanza had gone up the mouths of the shafts before the big bore was finished. 'Tis now nearly sixteen years since the tunnel was connected at the 1640 level of the Savage incline.

THE present extraordinary low rate of interest is illustrative of the abundance of idle money and the depression of trade.

TABLE OF CONTENTS.

ILLUSTRATIONS.—New Type of Vertical Compound Engine, 305. Motor-Driven Engine Lathe, 308. Head Works of the Amador Canal; New York Reservoir; The Bald Rock, Flume, 311.
 EDITORIALS.—Vertical Compound Engine; Miscellaneous, 305. Nevada at the Fair; Visit to the Union Iron Works; Miscellaneous, 306.
 CORRESPONDENCE.—Minerals of the Pacific Northwest, 306. Loss of Gold in Milling Ores, 308.
 SCIENTIFIC PROGRESS.—The Roar of Sun Spots; The Breathing-like Movements of the Earth's Surface; The New Metal; The Highest Windmill Tower in the World; Science and Americans, 312.
 MECHANICAL PROGRESS.—How Matches are Made; Glass Impervious to Heat; New Metal Cutting Saw; Items, 313.
 ELECTRICAL PROGRESS.—"Unknown" Causes of Fires; Electricity in Plants and Fruits; Items, 315.
 PRACTICAL INFORMATION.—To prevent Iron From Rusting; Where Scrap Iron Goes, 314. Warmth from Paper Clothing; Insurance and Gambling; Remedy for Insomnia, 315.
 THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 319.
 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 317-318.
 MISCELLANEOUS.—General Mining Notes; General News Notes; Personal, 307. Motor-Driven Engine Lathe; Book Notices, 298. The Limitations of the Gold Stamp Mill, 309. Chemical Theories About Formation of Nuggets; Origin of Gold Nuggets; The Burial of the Living; Items, 310. The Blue Lakes Canal; The Southern Negro's "Jack"; Be Wise and Richer; Items, 311. Coast Industrial Notes; Recent Patents, 318.

RECENT quotations of aluminum place the retail price in plates from \$1 to \$1.50. In ingots it sells at 80 cents, and in bars for horseshoes, forgings, etc., at \$2 a pound.

IN the interests of "economy," it is proposed to disorganize the Coast and Geodetic Survey. Such pranks are on a par with the "economy" of the idiot who burns down a costly structure.

THE effort at "tariff legislation" has become simply a contest among the different trusts and combines, a battle of the lobbyists, each trying to get all possible favor. It has become "a local issue."

SELDOM has a greater contrast been afforded between actual and assumed assets than in the case of the Pacific Bank of this city. When last examined by the Bank Commissioners their report was that the assets were \$4,774,758, and the liabilities \$2,884,157. Now it transpires that the liabilities continue at that figure while the assets have shrunk to \$2,902,338.

THE substitution of oil as fuel in the locomotives of the C., B. and Q. railway system is a noticeable movement. For some time an English railway has been using a fuel composed of gas, tar, creosote, coal dust and sawdust, but the Chicago, Burlington and Quincy affords, it is believed, the first instance of a prominent railway company resorting to oil exclusively for locomotive fuel.

THE town of Fairchance, Pennsylvania, seems to be misnamed. Working miners at Fairchance, whose only crime is a desire to labor that their wives and children may have bread, have been dragged from their beds, tied to posts and whipped by some of their former comrades who believe that their objection to labor gives them the right to punish any one else who wants to work.

THE recent death of Henry S. Ives illustrates a good many things. Twelve years ago he was working on a farm for two dollars a week. Then he got eight dollars a week as a New York office boy. When twenty-one he was getting fifteen dollars a week. He went on Wall street and made \$30,000 the first year. The next year he had secured \$2,000,000; the next he had worked the street for \$21,000,000. He died at 80.

THE Spokane Review doesn't like the Montana Miners' Union, and says: "If men are idle in the Cœur d'Alenes, it is because they will not work in these times of depressed prices for less wages than they were paid when silver was up to \$1 and \$1.20 an ounce. The great ore bodies of that section could employ 4000 men and pay them from \$2 to \$3 per day, but they cannot employ 400 men at \$3.50 per day. The Butte Miners' Union is alone responsible for the hard times now suffered by the people of the Cœur

d'Alenes, and indirectly by all the people of this section. In its mad fight against the impossible, it has caused labor to lose millions without one compensating cent. The strike there for impossible wages has hardly a parallel for stubbornness of folly. It is absolutely destitute of reason."

REGARDING the recent Supreme Court decision in the case of King vs. the Amy and Silversmith Consolidated Mining Company, a rehearing of which was asked, it is understood that the rehearing will be denied. The supposable ground for such declination is the undeniable fact that the court interpreted the law as it exists. Probably were the judges members of the other co-ordinate branch of government and empowered to make the laws they might be able to frame a statute that would not be so prolific of litigation.

THE American manufacture of tin plate is not in the languishing condition sometimes ascribed to it. During the three months ending December 31, 1893, thirty-nine firms manufactured 27,351,241 pounds of tin andterne plates; for the preceding three months the output by the same firms totaled 27,145,480 pounds. About sixty per cent of this was made from sheets rolled in the United States; of the firms twenty used wholly American plates, eleven American and foreign plates, and four used foreign plates exclusively.

FROM Boulder county, Colorado, comes details of "a new process" to treat low-grade gold ores. A series of filterers take the ore from the stamps, the ore coming in at the top, and gauged by water pipes running in, the free gold being caught in the first filter, the remainder being concentrated in the second. It is claimed that by a peculiar construction of the filterers a receiver saves 95 per cent of the gold without plates or chemicals. The process has been patented, and, if there is any merit in it will make a name for itself.

THE last lecture of the winter course of the Geographical Society of the Pacific was given last Tuesday evening by Hugh Oraig, the subject being "Reminiscences of New Zealand." The lecturer referred to the Maoris and their refusal to accept Anglo-Saxon civilization, and gave an interesting account of the Maori mythology, showing how closely it follows the Mosaic account of the creation and the flood, and other Biblical narrative. "The singular thing is," said Mr. Craig, "where did they get it, for they had no written records? This question has puzzled philosophers and learned men."

THE Executive Committee of the State Mining Exhibit at the Midwinter Fair have issued a final appeal to mine-owners everywhere throughout the State for aid in carrying on the exhibit till the close of the Exposition. As at present, the finances will be used up by June 1st. It would be a pity to close the exhibit during the last month of the Fair, but money is necessary to care for, pack and return the exhibits, and the request of the committee in charge is so manifestly reasonable and just, it is so clearly in the interests of all, that it is believed the matter need but be mentioned to elicit satisfactory response from all concerned.

THE Midwinter Fair drilling contest, under the auspices of the Mining Department, will take place at 3 o'clock next Tuesday afternoon. It is open to any miner on this coast. There is a prize of \$100 for the best single-hand driller; \$200 for best team of two drillers; \$300 for best team of three drillers, and second prizes of \$50, \$100 and \$150, respectively. The time for drilling will be fifteen minutes; all drills used by teams of two and three will be seven-eighths steel; drills used by single-hand drillers to be five-eighths steel; hammers not to exceed four pounds in weight; the work to be down holes in Rocklin granite. Considerable interest is manifested; there are numerous entries, and it is manifest that the best men will win.

TALKING of silver and exchange, the *Times of India* looks for a big falling off in shipments of silver to India. "In future," says that paper, "silver will scarcely be imported except for the purposes of art, hoarding, bartering and possibly for illicit coining. The quantity that will be absorbed in the arts can hardly be large enough to interfere seriously with the sale of council bills. As a bar of silver weighs nearly 85 pounds, it cannot be taken to an up-country railway station without attracting attention, so it will not suit the party intending to bury it underground to expose his wealth to his neighbors. It may be asked why he should not have his bar cut into pieces before taking it away from the Presidency town. The reply is that a bar which is cut up when put on the market fetches less than an entire bar; and as by settlement regulation the bar must be of nearly 2300 tolas, the purchaser cannot resell at a considerable profit if this metal is cornered."

"Hoarding, bartering and illicit coining" sound singular, but are illustrative of some of silver's uses in that far-off land.

IN a few days 40 mining men will leave this city, under the leadership of A. R. Hammond, for Central Africa on a prospecting tour. They comprise all necessary attaches, and plan to spend three years in Central Africa. They call themselves the South African Prospecting and Exploring Expedition. Each member must pay his fare and have \$500 besides for an outfit. They expect to go fully equipped, even to taking a small stamp mill, and propose to go where no white man has ever trod. J. O. Sissons is the assayer and Richard Lewis the geologist.

THE Idaho *Avalanche* says that the new milling process is of inestimable value to the War Eagle miners, and that the Poorman Consolidated are now milling their ore at a cost of about \$2 a ton, and saving everything. It gives the gain between the old process and the new, taking 100 tons of \$100 ore as a basis under both processes:

OLD PROCESS.	
100 tons @ \$100, assay value.....	\$10,000
Value saved, 80 per cent.....	\$8,000
Milling @ \$13 per ton.....	1,300
Net to mine-owner.....	\$6,700
NEW PROCESS.	
100 tons @ \$100, assay value.....	\$10,000
Value saved, 98 per cent.....	\$9,800
Milling @ \$5 per ton.....	500
Net to mine-owner.....	\$9,300
A difference of \$2600.	

A MINING SUIT is being at present conducted in the United States Circuit Court in this city of considerable interest to the mining public. The litigants are the Consolidated Gold Mining Company and the Champion Mining Company. The property in dispute is located on Deer creek, Nevada county, Cal., and is valued at from half a million to a million dollars. The Wyoming people claim that the defendants have, during a number of years, taken out about 50,000 tons of ore from veins asserted to be the property of the plaintiff, and ask for the value of the ore, and for an injunction against the further working of the vein in question by the defendants. The claim of the plaintiffs is denied in toto by the defendants, who assert that the plaintiffs have no extra lateral rights, and that they are working their own property in the extraction of the ore in the ground in dispute. The suit is in equity, and will take some time to determine.

Visit to the Union Iron Works.

Secretary of the Navy Herbert and a party of invited gentlemen were the guests of the Union Iron Works last Tuesday. The tug Fearless brought the Secretary and his party down from Mare Island accompanied by the Fifth Artillery Regiment Band from the Presidio. Upon arrival at the Union Iron Works the entire party disembarked. Mr. Henry T. Scott showed the distinguished visitors through the works. They were taken on board the Olympia, which the Secretary of the Navy examined with considerable interest and commendation, having many things to say of the Union Iron Works and the work being done there, which were commendatory and deserved.

Nevada at the Fair.

Last Tuesday, the 15th, was "Nevada Day" at the Midwinter Fair in this city. It was a fine occasion, finely celebrated by thousands of present and former residents of the Silver State. Nevada is the only State having its own building on the grounds, and it was at first intended to have the literary part of the celebration in the building, but the thronging thousands made that impossible, so all outdoors was utilized. Speeches were made by distinguished citizens, music specially written for the occasion was performed, songs were sung, and there was a good time generally. Hon. H. G. Blaisdell, the first Governor of Nevada, and R. K. Colcord, the present Governor, were among the speakers. In the course of his remarks Gov. Colcord said:

Nevada may be said to be a child of California, as the greater part of its earlier settlers were Californians, and, like the pioneers of '49, they were of the best material, and braved the many hardships and privations in crossing the mountains of perpetual snow and entered what was then a sagebrush desert inhabited only by hostile Indians. Their work in the development of our mines was phenomenal, and for 30 years our people enjoyed a wonderful degree of prosperity. Our miners and laboring men received a higher rate of wages than was ever before paid for the same class of labor in this or any other country. During this time our mines yielded nearly \$600,000,000 in gold and silver bullion, which we think a very fair showing for a State having a population of about one-seventh that of the city of San Francisco. In common with all other silver mining communities, our mining interests are now suffering in consequence of adverse, and, we think, unwise legislation, which will be corrected when the American people decide to dispense with the services of selfish, partisan politicians, who serve their masters, and elect in their stead honest, able, patriotic American statesmen, who will labor for the best interests of America and Americans rather than for foreign capitalists.

General Mining Notes.

THE Con. Virginia works are now lit by incandescent electric lights.

AN English syndicate is forming to work alleged gold mines in Devonshire, England.

JAS. L. FLOON has acquired control of the Allison Ranch mine, near Grass Valley.

W. C. HADLEY of Albuquerque, N. M., has bought the Tennessee mine at Chloride, Ariz.

THE Rand mines, limited, South Africa, contributed one-sixth of the world's gold product last year.

THE Old Glory gold mine near Tucson, Ariz., is to be refitted throughout and worked for all that is in it.

It is thought that during the present month the Anaconda mine will produce 13,000,000 pounds of copper.

THE "Maggie G" mine in the Black Mountain District, Colorado, is reported sold to El Paso parties for \$160,000.

THE Washoe mine near Butte, Mont., was sold at referee's sale last week for \$50,000.50. J. A. Legget is the purchaser.

J. E. NICHOLS of San Jose has control of the Centennial gravel mine in Nevada county and will resume operations and push work ahead.

THE James G. Blaine Mining Company has been incorporated to develop mining properties in the White Horse mining district, in Washoe county, Nevada.

WITH sixty stamps the output of the Robinson Gold Mining Company of Johannesburg, South Africa, for twenty-eight days was \$150,000 over all expenses.

THE Reno Reduction Works have been leased by Russell, Bradley, Foley & Co. for six months. It is the intention to work 5000 or 6000 tons of the English mill tailings at the works.

THE latest shipment from the Tillie Butzel mine, at Boulder, Col., yielded the owner over \$450 per ton. Twelve men during the month of April raised ore which netted the owners over \$5000.

NATHAN MILLARD and three companions of Campo, Col., have perished miserably on the Cocopah desert, in San Diego county, where they were making an ounce a day when they died of thirst and exposure.

WEE HON PEUNK, once a millionaire Chinese miner in Arizona, and again heard of in South Africa, where he went with his American wife to make another fortune, has bought an interest in the Kaaraji diamond mine.

THE largest bullion shipment ever made from Park City, Utah, occurred on the 8th inst., there being 105 bars, containing 92,323 34 fine ounces. The *Record* says the express car was full of it and it attracted general attention.

THE Baldy Queen Mining and Smelting Company has organized at Trinidad, Col., with a capital stock of \$70,000. This corporation has several claims in the Moreno district, in New Mexico, among them being the Grand View.

THE dead body of John L. Tinnian, an old Colorado miner, was found near Grand Junction, Colo., last Monday. It is thought that he was murdered and robbed. His brother was formerly Surveyor of Port of San Francisco.

JAMES O'BRIEN, an employe in the Anaconda mine at Butte, Mont., had a very narrow escape from death last week. He stepped into an open shaft and fell 100 feet. He received many painful bruises and was badly cut, but his hurts were not fatal.

W. E. LINDBER, the locator of the travertine ledge in Mono county, has sold the quarry to a party of capitalists, who propose to ship the travertine to all parts of the United States and Europe. They say the discovery is one of the most important ever made.

THE average wages in the Johannesburg, South Africa, mines are reported to be as follows: Miners, working machine drill, per day \$5; miners, working Kaffirs, \$3.75; blacksmiths and good drill emitts, \$5; fitters, from \$4 to \$5; engine drivers, from \$3.75 to \$4.75. Engine drivers average from \$120 to \$150 per month of thirty days, chiefly twelve-hour shifts.

PROF. PRICE's experiments in smelting nickel (for the first time on this coast) have been successful. The first charge resulted in 200 pounds of metallic nickel, worth 50 cents per pound. The ore has heretofore been sent to England. It is from the Oregon nickel mine and can, it is believed, be treated successfully in this city.

WILLIAM PRINCE, an expert mining engineer, recently went to Bolivia in the employ of an English syndicate, to develop gold mines. While there he made a fortune on his own account. He lived alone at his mine, and it now transpires that he has been robbed and murdered by two men who stopped at his place ostensibly for a night's lodging.

It is reported that rich gold placer diggings have recently been discovered in the interior of the peninsula of Lower California. The placers are located eight miles east of the volcano springs, at a place called the Tules, and about 160 miles south-east of San Quintin. There is said to be plenty of water, and the miners are taking out from half an ounce to two ounces a day.

A CORRESPONDENT of the *Phillipsburg Mail*, writing from South Africa, says: "The only thing new now is a law which compels a prospector to get his claims surveyed within one month after locating; it only costs £50, and any prospector always has \$250 that he don't need. It is a great idea to have to pay that sum before one knows whether his ground is any good or not."

THE Alaska Treadwell Gold Mining Company announces the March cleanup as follows: Shipment of bullion, \$37,322; ore milled, 13,201 tons; sulphurets treated, 190 tons; of bullion there came from sulphurets \$5,464. The estimated gross expenses for the month have been \$21,388. The net profits available for dividends for the first ten months of the present financial year are about \$338,000.

AN exchange says that a rediscovery of the mine worked by De Soto and his followers 300 years ago has probably been found. W. C. Padget, a man who operates a sawmill in the mountains of Georgia, has discovered some relics in the shape of stone mortar and other implements. He secured the services of an old mining engineer to inspect the place. In one of the excavations they found the spur of a quartz vein, in which

there was a considerable quantity of gold. The old engineer said that it was a valuable find, and believes it is the exact spot where De Soto and his followers located and mined for gold and silver 300 years ago.

IN 1892 the quantity of gold exported from British Guiana was 131,425 ounces. So far the gold has been obtained by alluvial washing, but mining has now been started on quartz reefs in the northwest district, on the Barina, and also on the Demerara rivers. About half the output for 1893 was obtained from the district, comprising the Potaro river, which district alone gives employment to upward of 3000 men.

F. CHAPPELL, well known in Placer county, has bought a controlling interest in the El Encino mine in Chili Gulch, Calaveras Co., and is pushing a bedrock tunnel 1000 feet to tap the channel at the southern point of the claim; then, by extending the tunnel 900 feet up the channel, the bottom of the present pump shaft will be drained, thus again opening the Old Blue lead which paid so handsomely when water drove the miners out.

IN New South Wales there is a rush to the Wyalong gold fields. Another rush is reported to Coolgardie in West Australia. It is estimated that 20,000 men have gone to each place. Extraordinarily rich ore is found; but the majority will experience the usual disappointments. The Coolgardie gold fields are separated from settlements by over 200 miles of desert, destitute of water. Two miners who left Parramatta returned and showed 24 pounds of solid gold, 13 pieces in all, the nuggets varying from 37 ounces to 18 ounces, which were got out of the earth at Kurnalpi not more than a foot down. All the gold was picked up in four or five days.

A PARTY of capitalists have located four miles of the south fork of Clearwater for placer mining, commencing at the reservation line and running up stream. They propose to work the bed of the river by means of steam machinery, which forces a jet of steam from a bucket on the bedrock, and by means of another stream of cold air, condenses the vapor and thus creates a vacuum, which is filled by the sediment on the bedrock. The bucket is then hoisted and the contents are prevented from escaping by a valve. On arriving at the surface the gravel is washed by ordinary placer process. The machine is the invention of an old *Coeur d'Alene* named Walker, and was tested some years since on Feather river in California.

THE Tucson, Ariz., *Citizen* says: "The much desired free coinage of silver is somewhat after the Mexican plan. Every State has its own mint, or perhaps two or three of them, as in Chihuahua. The minting is done under the patronage of the Government, but by no means is the money minted by the Government. A London firm has the contract. The mints are to the American eye, and judging from the work turned out, ramshackle affairs. Thither the miner goes with his hurras laden with silver bricks. His silver is weighed and the money coined out for it. Or, as is often the case, should money be short, he waits a day or two for his grist to beground. Then he takes his new silver pesos and praises free coinage."

WHAT a pity it is, says the *Australian Mining Standard*, that some systematic effort is not made to give us the benefit of the cyanide process of treating tailings. There are immense quantities of tailings in different parts of the colonies that ought to pay well for treatment, and although we may not achieve anything like the wonderful results attained in South Africa, we ought to be able to recover an appreciable quantity of the gold which has been allowed to flow away owing to poorly equipped batteries or to special difficulties in the way of saving fine gold. The Witwatersrand mines are now getting nearly 40,000 ounces of gold per month from tailings, and some of the companies put through many thousands of tons of stuff every week and make a handsome thing out of the 50wt average return.

SUPERINTENDENT ABADIE reports concerning the North Star mine near Grass Valley that the ore crushed at the North Star mill contains about four per cent of sulphurets. Their average value is \$53.55 per ton, and they have yielded in seven years a total product of \$236,756.63. The concentrates are sold to the local chlorination works. From the concentrating machine the pulp escapes as tailings, containing more or less gold, notwithstanding a high percentage saved of the ore value (reaching 94 per cent under favorable conditions). At the present time there is in operation a simplex rotary amalgamator, treating ten tons of tailings per 24 hours. Results obtained thus far have reduced the loss in the tailings 32 cents per ton. The mill is operated entirely by water power, notwithstanding a high rate per available horse power; the cost of power per ton of ore crushed has not exceeded \$0.32. The water used has previously been utilized by the Original Empire Mill and Mining Company under a head of 450 feet. At the North Star the effective head is 273 feet at the mill. For the year just concluded, Mr. Abadie says the gross production of the mine foots up \$355,757.04. He shows that the cost of milling a ton of ore on the average for the past seven years has been \$0.816, of which \$0.323 was for labor, \$0.320 for power and \$0.168 for supplies.

Personal.

E. H. RUSSELL, of Park City, Utah, is in the city.

MAJOR POWELL has resigned as chief of the U. S. Geological Survey.

J. J. HALPIN, general manager Brunswick Mining Company is at Grass Valley.

JAS. BENALLACK has been re-elected superintendent of the Central North Star mine at Grass Valley.

THOS. CARLISLE, a well-known mining man has gone to southern Oregon to develop a newly opened mine.

JOHN ELY, who with "Uncle Billy Raymond" had so good a thing at Pioche, Nev., twenty years ago, is now in the Cochiti district, New Mexico.

EX-SUPERINTENDENT JOHN HANLY, of the Old Dominion mine, Stevens county, Washington, is now in Alaska, where he has struck it rich in a good mining property.

SECRETARY OF THE NAVY HERRERT has been visiting this vicinity for the past week. He recommends an additional dry dock at Mare Island. He was very complimentary to our local manufacturing. He is now in Portland, and after viewing the proposed naval station at Port Orchard, Wash., will return to Washington.

General News Notes.

THE Senate has shelved the Chinese treaty.

THE President's tariff bill still hangs fire in the Senate.

TO DATE 1,450,000 have been admitted to the Midwinter Fair.

THE Washington, D. C., association of '49ers had a picnic yesterday.

A NEW French company is being organized to complete the Panama canal.

A MILLION-DOLLAR FIRE destroyed Talmage's Brooklyn Tahernacle last Sunday.

LAST week's foreign shipments of gold from New York aggregated \$6,000,000.

THE little town of Forest City was almost totally destroyed by fire last Sunday morning.

ON Sundays and after 5 P. M. the admission to the Midwinter Fair is now twenty-five cents.

BLANN, of Missouri is being boomed for the presidential nomination on a silver platform.

LARGE numbers of counterfeit Wells-Fargo money orders are being circulated in the Eastern States.

FOERCASTER PAGEZ says that the State rainfall is being increased by tree planting, cultivation, etc.

THE revenues of the Government for the last ten months have fallen \$65,400,000 below its expenses.

SAN JOSE has spunkily and sensibly secured sentence for three years in the penitentiary for a bank wrecker.

AN incendiary fire in Boston last Tuesday night burned \$1,000,000 worth of property and left 2000 poor people homeless.

BUSINESS failures, with liabilities amounting to \$20,000,000, have occurred in Buenos Ayres since the 1st inst., and others are considered propable.

UNITED STATES SENATOR HUNTON of Pennsylvania was offered, and of course refused, seventy-five thousand dollars for his vote on the pending tariff bill.

ANOLPH SUTRO has fenced up the Cliff House and will charge 25 cents to see the seals. He will present Sutro Heights to the city of S. F. if a five-cent railroad fare is guaranteed.

WILLIAM B. COUP, charged with killing Z. Root in Long Canyon, two years ago, committed suicide in the Auburn jail last Wednesday by hanging himself with a handkerchief.

THE Bank Commissioners report less than \$70,000 on hand in the Pacific Bank. The claims against the bank aggregate \$600,000. The Commissioners hope to pay a five per cent dividend soon.

THE Appropriation Committee in the House of Representatives recommends a large appropriation to prior 10,000 copies of the record of the navy of the Confederate States during the Civil War of '61-'65.

SALT LAKE CITY has disposed of its famous gold-bearing bonds—interest and principal both payable in gold—at a premium of one per cent. The total issue, amounting to \$800,000, was bought by Chicago people.

THE San Francisco Custom-house is to be investigated. The notable falling off in the revenue on opium will be the principal thing investigated. At one time the duty amounted to \$1,400,000; it is now \$600,000.

THE number of Chinese registered in the entire country is 105,742, of whom 67,989 are in California and Nevada, 4701 in Montana, Idaho and Utah, and 1803 in Arizona. The Chinese population by the last census was 107,573.

LEN HAEIS, the Southern Pacific detective, was shot and mortally wounded at Boulder Creek, Cal., last Tuesday evening in the attempt to capture a desperado who had entered the railroad station at that point for the purpose of robbing it.

L. L. LEWIS, a Butte, Montana, mining superintendent, has been arrested in Chicago. Charles F. Stockes, proprietor of the Stockes Manufacturing Company, lost \$12,627 and a \$300 diamond at poker, while playing with him and three of his friends.

INVESTIGATION of the Northern Pacific road at New York shows sharp work on the part of Henry Villard et al. They bought a railroad whose capital stock was \$750,000, increased this to \$2,000,000, and sold it to the Northern Pacific for \$1,402,000.

CONCERTED action of the health officers of Illinois, Ohio, Wisconsin, Michigan and Indiana is depended upon to stamp small pox out of Chicago and the West. Extra physicians and extra inspectors are attacking the plague in the sweatshop districts.

OF 763 men in Kelly's industrial "army," 449 are American born and 314 foreign born. Of these 58 are from Germany, 30 from England, 28 from Ireland and 12 from Scotland. Politically 218 are Republican, 196 Democrats and 240 Populists, while nearly 100 were pinto.

ANOTHER private silver-dollar factory has been stopped at Kansas City. Missouri people are so fond of silver that in the absence of governmental ability to furnish the regularly stamped article, they accept a good imitation till Uncle Sam stops the surreptitious mintage thereof.

COXEY is spoken of by the London *Daily News* and the *Pall Mall Gazette* as an Ohio Congressman. He has been nominated by the Populists for Congress from the Eighteenth Ohio District. He says that his army will remain near Washington until Congress appropriates \$500,000,000 to furnish work for the unemployed.

THE report for April of the California State Board of Health announces a death rate in the State for that month of 1.25 per thousand, or 15 per thousand per annum. This percentage is based on reports from 86 towns aggregating a population of 893,453 and having a mortality for April of 1118. There were 210 deaths from consumption, 101 from pneumonia, 36 from bronchitis, 14 from congestion of the lungs, 8 from diarrhoea, 8 from cholera infantum, and 73 from other diseases of the stomach; cancer caused 31 deaths, and 96 were the result of diseases of the heart.

Loss of Gold in Milling Ore.

TO THE EDITOR:—The diversity of opinion existing in regard to the amount of gold loss in milling our ores at present is traceable to the tendency to generalize from special results on special ores. It does not follow with ores of widely different character that a heavy loss of gold in milling a special ore is proof positive of a similar result on all ores. The subject on hand presents few difficulties to arrive at correct results. We fortunately have excellent automatic sampling machines at present, which leave no uncertainty as to the fairness of assay samples of our tailings, and all it requires is for the millman to use the facilities on hand to get a true knowledge of the amount of his losses.

In 1873 the writer investigated the loss of gold in one of the best mills at the time existing in the State, and provided with efficient concentrating appliances, to incorporate the results in his report to U. S. Mining Commissioner, R. Raymond, on the "Treatment of Gold Bearing Ores in California." The samples were carefully taken at the end of the tail sluice as follows: The buckets were allowed to run nearly full every half hour, and the sands were settled exactly three minutes. The water, holding in suspension the slime and float gold, was filtered off on a large paper filter capable of holding the whole contents of the bucket. The coarser sands were filtered on a separate filter, sized

concentrates 25 per cent on the same rock. Messrs. McDermott and Duffield, in a pamphlet on "Losses in Gold Extraction," in criticizing our Government Reports in which former losses do not agree with later results, lose sight of the above facts. Hasty conclusions on insufficient grounds certainly detract from the value of their otherwise excellent monograph on the subject.

Not all of our ores, however, are as easily managed in milling as the ores of the Grass Valley and mother-lode series. This is especially the case with the gold ores occurring in the grano-diorite of the foothills, bearing a considerable amount of silver compounds. The difficulties of copper-plate amalgamation and thorough concentration are quite serious, occasioning a much heavier loss of the precious metals in milling and compelling the treatment of the resulting concentrates by smelting.

The practice of milling in Colorado appears to preclude the close working of its ores as evidenced by the results of former investigation by Mr. Reichenegger in his report to the U. S. Mining Commissioner in 1870, who notes a loss of 50 per cent of the gold, while Mr. Phil Argall of Denver, in his interesting discussion on paper read by T. A. Rickard before the International Engineering Congress, notes a present loss of 40 per cent in milling in Gilpin county—not a very encouraging gain in efficiency of the milling process during the last quarter of a century.

In regard to the most efficient weight of stamps referred

four women and two ten and twelve-year-old children, who will walk the long distance of 600 miles. The women wore men's trousers as well as the ordinary dress.

"Last year the miners got a good deal of gold," said Mr. Sylvester. "I know quite a number who cleaned up from \$5000 to \$8000 and \$10,000 each, and this has awakened an increased interest and caused those women to go in and join their husbands. The gold mines about Juneau, especially on Douglas island, are about as usual. The Treadwell is working 200 men. They are a little short of water there and are just now running a little lightly. The New Mexican Company, also on the island, has one 60 stamp mill just about completed and ready to start."

Motor-Driven Engine Lathe.

We present herewith an illustration of a lathe in which the design includes an electric motor, taking the place of the usual cone pulley. The lathe is reversed and the speed regulated by the movement of rod A, this, with the back gears arranged as usual, giving a much wider range of speeds than can be obtained by cone pulley, but a much more finely graduated speed; in fact, the speed may be anything from the highest to the lowest desired.

The armature of the motor is wound on a phosphor bronze spider with a carrier disk which revolves freely on a spider the same as a cone pulley.

MOTOR-DRIVEN ENGINE LATHE.

and separately assayed. The slimes containing the float gold represented 19 per cent of the solid contents of the mill water and showed a loss of three and one half per cent out of a total loss of twenty-seven per cent, or, with other words, about 13 per cent of the loss could be attributed to float gold. This result was obtained by crushing through a No. 6 punched Russian screen, the method of milling being at the time the blanket system.

Since the general introduction of battery amalgamation and broad oscillating amalgamated copper plates behind the apron plates, quicksilver and amalgam traps and concentrating machinery, the percentage saved in our mills has steadily increased, while the cost of milling by the introduction of grizzlies, rock breakers, self-feeders and automatic vanners has in similar ratio diminished. Mr. J. H. Hammond gives the present extraction of some of the best mills in his care after careful automatic sampling and assaying over a period of a year at from 86 to 90 per cent of the assay value, and there is no reason to doubt the correctness of his figures.

Superintendents of other gold mines in this State who keep a close watch on their mill losses by frequent sampling and assaying of the tailings—including all the solid contents of the mill water, not sands alone—report similar losses ranging from 10 to 15 per cent of the ore value at present.

The steady improvement in gold extraction in California is patent to all who were connected with the treatment of the concentrated sulphurets from the early days of quartz milling. The value of concentrated sulphurets, though cleaner or freer of quartz sands by true concentration than formerly, is continually decreasing on account of improvements in gold-saving appliances in front of concentrators. The writer knows of a case in which the introduction of a certain amalgamating device decreased at once the value of

to by an esteemed cotemporary in one of your late issues, the writer's experience at the Eureka mill, Grass Valley, in 1870, does not coincide with his view—that a 650-pound stamp is the right weight for milling our hard quartz.

The following facts will throw additional light on this subject: A battery of 20 stamps, weighing 850 pounds per stamp with 61 drops of ten inches per minute, crushed 48 tons of hard quartz in 24 hours, while a battery of 20 stamps weighing 700 pounds per stamp, with 68 drops of ten inches per minute, crushed 38.4 tons of the same rock through a No. 6 screen. The proportion of power necessary to do the work of the heavier to that of the lighter stamps is as 850x61, 700x68, and the work expected therefrom would be as nearly 42 tons from the heavy to 38.4 tons of the lighter stamps; but the former crushed 48 tons—an additional quantity of six tons in favor of the heavy stamps. However, it must be admitted that on softer rock, delivered in small size to the self-feeder and with other collateral conditions, the result may be more in favor of lighter stamps. Comparative tests generally impossible in the rush and hurry of milling practice should be a proper subject to the more leisurely investigation in field practice of the metallurgical faculty of our mining schools.

Auburn, May 16, 1894.

G. F. DEETKEN, M. E.

Women Going to Alaska.

Among the arrivals from Alaska yesterday, says the *Examiner* of the 17th, was E. O. Sylvester, proprietor of the *Alaska Herald* at Sitka and the *Journal* at Juneau. Mr. Sylvester says the far northwestern part of the continent seems to be the only section not affected by hard times. There is, in fact, unusual prosperity there, so he says. Already over 300 miners have passed in via Juneau for the gold mines up the Yukon, and among them were three or

It is surrounded by pole pieces inclosed in housing, the lower half of which is cast in one piece with head stock proper, to which the upper half is substantially fitted and secured by means of four bolts. This construction forms what is known as an ironclad motor, entirely free from external magnetism. This is necessary in order to keep small particles of steel and iron from adhering to the lathe, making it impossible to keep it clean.

Among the advantages secured by such an application of electricity are that tools may be placed independently of fixed conditions overhead, such as shafting, cranes, etc., and with regard to the arrangement best suited to handle the product most conveniently, and the operator has the best control of his machine, especially when a variable speed is necessary.

The head screw is placed on the inside of the bed, directly under the front V, and is inclosed in a brass tube, protecting it from dirt and chips. In this position it takes hold of the carriage directly under the line of strain, and obviates that twisting tendency which is so common in lathes where the screw is placed on the outside of the bed. All the feeds of the carriage can be thrown in and out or reversed from the front of the apron. This is a particularly desirable feature, inasmuch as the operator is not compelled to leave his work, and it does away with the complicated gearing in the head-stock. The carriage is provided with a stop which throws out the feed automatically, and may be set at any point along the ways. This is very convenient for turning or boring a given length, and also prevents the lathe from being damaged by any carelessness of the operator. The spindle is hollow and of large diameter; the boxes are made from the best phosphor bronze, and are provided for taking up wear.

This lathe was built by the Lodge & Davis Machine Tool Co., of Cincinnati, O.

The Limitations of the Gold Stamp Mill.

IN THREE PARTS—PART III.

Continued discussion of the paper of Mr. T. A. Rickard, read at the Chicago meeting of the American Institute of Mining Engineers, August, 1893.

In his criticism of my statement that the retention of the pulp within the mortar, long after it is pulverized to a fineness permitting exit through the screen, has been used by the Gilpin county millman to assist him in obtaining the conditions which he desires, Mr. Argall has missed the main principle, repeatedly emphasized by me, of the milling practice which he is discussing. The methods in vogue in Gilpin county originated in no idea of concentrating; if they had, then the excessive slitting of the pyrite, due to the deep discharge, would be a stupid blunder. On the contrary, however, the practice of the district is founded upon the principle of using the mortar, not only to crush the ore, but also, as far as possible, to make the mortar an amalgamating machine. The introduction of percussion tables for concentrating the pyrites in the tailings is comparatively recent. The millman's intention is to save as much gold as possible inside the battery, and to do this by retaining the pyrite (with which the gold is mainly associated) inside, until a separation has been brought about; and these ideas are carried out by having a roomy mortar, a long, slow drop, and a deep discharge—more especially the last, which assists in procuring the condition he considers the most favorable to his purpose.

A statement was made, more than once, at the Chicago meeting, which does not, however, appear in the printed discussion, namely, that while the California type of stamp mill has been introduced in mining regions all over the world, that of Gilpin county has not passed outside its own habitat. This statement is not quite accurate, since mills of the Colorado type have been successfully used in Dakota, Montana, Arizona and Idaho; but, broadly speaking, it is no doubt correct to say that the California type is, by far, the more widely employed. Upon this fact is founded the suggestion that the methods of "the little kingdom" of Gilpin are not thought worthy of imitation. In commenting upon this matter, I trust I may be absolved from any charge of prejudice, since I have used both types of mills successfully, and have endeavored to discuss the advantages and disadvantages of both fairly. The explanation of the fact just referred to is somewhat as follows:

The methods in vogue at Central City and Black Hawk were evolved under unusual conditions, and have been retained under peculiar circumstances. The first mills introduced, in the early "sixties," were modeled on the Californian type, and had a quick, short drop and a shallow discharge. While the mines were still in the gossan, or surface quartz, everything went well; but as soon as the unoxidized pyritic ores were reached the extraction began to diminish fast, and finally, this diminution nearly put a quietus to stamp milling. Then the smelter came to the rescue, and prevented the cessation of mining during the years which elapsed until the millmen, by a long series of experiments, arrived at the conclusion that a long, slow drop, and a deep discharge, gave the conditions most favorable to the successful treatment of their ores. When the present methods were adopted, nearly twenty-five years ago, there was no market for low-grade iron pyrites, and the ore, although containing from 10 to 25 per cent of sulphides, would give up a large percentage of its gold contents when crushed in the deep mortars which had come into use as the result of a hard-bought experience. The old methods have been retained, but with the addition of percussion tables, because now the smelters charge very low rates of treatment for pyritic concentrates. Smelting charges are \$4.50 for concentrates, and \$12 for crude ore. Railroad freight to-day (from Black Hawk to Denver) is \$1.50 per ton on material worth less than \$30 per ton, and \$2 per ton for higher-grade stuff. Small coal ("mine-coal") is delivered at the mills for \$1.60 per ton. These are some of the conditions which have tended to perpetuate a milling practice which is, in many respects, out of date.

On the other hand, the methods of Gilpin county have not been adopted extensively elsewhere, because it is rarely that ores rich in pyrites are found to be comparatively so free-milling. The Californian mill, moreover, in its typical form, is a crushing machine, adapted to preparing the ore cheaply and rapidly for a great variety of after-treatment, by plate amalgamation, blanket saving, pan amalgamation, concentration, lixiviation, etc. It is, as a crushing machine, having its parts so arranged as to give a maximum of automatic handling of the ore, that the California mill is first of its kind. Compared with it, in this respect, the Gilpin county batteries are clumsy and incomplete; but as an amalgamating contrivance for the treatment of a particular class of ore they were well conceived, at a time when amalgamating methods had no competitor in cheap smelting.

Thus, after all, we do but return to the truism, which is often forgotten in these generalizations, that the milling practice to be introduced at any mine or in any district must be suited to local conditions, the most important of which is, of course, the character of the ore.

W. L. AUSTIN, Denver, Colo.: A word as to the current fable of which Dr. Raymond speaks. Stamp stems being among the "working parts" of a mill are, therefore, included by Dr. Raymond in the category of the iron that does not crystallize. It will have been observed by any one who has operated a new stamp mill of the California type, with stamps dropping from 90 to 100 times per minute, that after his battery has been running 12 to 18 months the stamps stems begin to break. Moreover they break off, as a rule, right above the stamp head, though occasionally they snap off just under the tappet, and often it becomes a serious undertaking to remove the ends of the stamps from these heads or "hosses." On account of these breakages the stems are made tapering at both ends, so that when one end has broken off it can be reversed. In due course of time a similar mishap usually overtakes the other end. In many cases the mutilated stem is then laid aside as a problem for some future manager to solve, and new ones are ordered from the manufacturers. Now, the breakages may, as Dr. Raymond says, not be due to crystallization of the iron, for, properly speaking, the iron (which should be the best quality of wrought iron) originally used in their manufacture is crystallized to begin with, but during the pounding which the stamp has been doing, some molecular change has taken place, changing the fiber into a structure coarsely granular in appearance. That such a change should take place is quite conceivable, for these stems are submitted to an unpleasant amount of jarring. The $3\frac{1}{2}$ -inch stem weighs 363 pounds and the $3\frac{3}{4}$ -inch stem 390 pounds, while the aggregate weight of stamp, including stem, head, shoe and tappet, is over 850 pounds. Such a weight falling six inches 100 times a minute for 300 days in the year, finds no parallel case in pump rods or the connecting rods of engines. As would be expected, when the shoe is allowed to fall on the die the life of the stem is shortened. The fact remains that the stamp stems do break, and the iron has the appearance of being what, in the absence of a better term, is technically known as "crystallized." There is a class of men engaged in milling throughout the West who have been brought up in mills and have made a business of running them. It is a common practice among these operators to take the stamp stems out of the batteries and anneal them by heating, and hammering them when the limit of safe working has been reached. These men are not chemists, and had once their little foibles, among which was the harmless use of sage tea and similar concoctions in their amalgamation departments; but they are first-class, practical mechanics and their experience and opinions in these branches of milling are entitled to respectful consideration. Among such men as these the fable spoken of by Dr. Raymond is still current. At one mill which was under the writer's charge for a while, there was a man employed who was classified as mill blacksmith. He was the highest-priced man carried on the pay roll, and it was his special duty to repair the ironwork about the mill, anneal stamp stems, etc. Considering the appliances at his command he managed to perform what might be termed feats of blacksmithing, and among such was the piecing out and welding of $3\frac{3}{4}$ -inch stamp stems in an ordinary horse-shoeing forge, so that they afterward withstood the wear and tear of the battery. He always paid great attention to the careful annealing of such work, for it is the experience of millmen that stems thus treated last much longer than when such precaution is neglected. To have rendered this annealing necessary, the fiber of the iron must have undergone some change by the long-continued jarring which the stems had received. One can easily satisfy one's self of the extent of this jar by taking hold of a stamp stem while in operation. It will be found to quiver violently. If the molecular change which takes place among the particles of iron in a stamp stem after long and continuous use, by which the fibrous texture is altered into a granular one, may not be termed a crystallization, what is the proper expression to employ for such a phenomenon?

DR. RAYMOND: Mr. Austin's remarks indicate a misconception on his part of the meaning of my statements concerning the alleged "crystallization" of iron by vibration. It was not in the least my intention to quibble over a word. If I were so disposed, I should take exception to his present assertion that the wrought iron of which stamp stems are made is "crystallized," to begin with. The question in my mind, as I think a careful reading of my remarks will convince Mr. Austin, was, whether there is really a molecular change produced by vibration in wrought iron or steel. When Mr. Austin triumphantly inquires what is the proper expression, if "crystallization" is not, to describe such a molecular change, he simply begs

the question. It will be time enough to discuss the name when the existence of the phenomenon has been demonstrated.

Before considering the evidence as to that question adduced by Mr. Austin, I would recall that my own criticism was made upon the sweeping statement of Mr. Argall, that "vibration under all conditions will crystallize iron." This I pronounce to be, "beyond question, incorrect," and to this, my only unqualified assertion on the subject, Mr. Austin's argument does not apply. If his evidence proves anything, it proves only that iron is sometimes thus affected by vibration.

As to this more limited proposition, I must frankly say that I see no conclusive force in Mr. Austin's argument. The one fact upon which it rests is the breakage of stamp stems after 12 to 18 months' running, and the granular appearance of the fracture. But the fracture of a fresh bar of iron can be made to appear granular without any prolonged previous vibration, by the condition of the fracture itself. A granular fracture does not prove an altered structure. If the vibration theory were correct, the rest of the stamp stem ought to be more or less altered in structure; and, indeed, other parts of the stem ought to be more affected than the parts where the breakages usually take place, for the two places mentioned by Mr. Austin, namely, "right above the stamp head" and "just under the tappet," are precisely the points of minimum vibration. They are the points of maximum stress, due to the checking of vibration by the stamp head or the tappet.

Now, it probably never occurred to Mr. Austin, or any of the practical millmen on whom he relies, to find out whether the parts of the stem which vibrate most freely are molecularly changed by such vibration; but some experiments of this kind which have been made have revealed no such alteration.

The fracture of iron under repeated stresses, no single one of which will produce visible rupture, is a very different proposition, and does not necessarily involve molecular change. It is more probably due to minute ruptures between the particles of the metal, which finally aggregate to constitute visible fracture.

I cannot admit that the vibrations in a stamp mill are more severe or more likely to produce molecular change than those to which railway axles, marine shafts and locomotive connecting rods are subjected. In these departments, quite as much as in stamp mills, the notion of "crystallization" by vibration is an old one, and the evidence in its favor is essentially that which Mr. Austin adduces, namely, the granular appearance of fractures, which, taken by itself, is quite inadequate.

If vibration produces molecular change, why should previous annealing prevent that change? As it would be manifestly impossible for Mr. Austin's mill blacksmith to anneal the whole of a stem in a horse-shoeing forge, it must be that he annealed only the part which he had welded, which would be the very part out of which he had taken all effects of previous vibration. Such an annealing was very proper to remedy the unequal strains caused by the welding process itself, and to prevent the piece from breaking under stress or shock. But as it left untouched the rest of the "crystallized" stem, it can scarcely be considered regenerating a fibrous structure. Moreover, a fibrous structure cannot possibly be produced by annealing.

In short, while I have never denied the possibility of molecular change in iron due to vibration, I must continue to regard the proposition as unproved, and the burden of proof as resting upon those who assert it, in the face of numerous experiments and careful tests which indicate the contrary. Mr. Howe's conclusion, after a patient analysis of much evidence, is:

"To sum up, while vibration and shock often cause rupture under light stress, and while it is proverbially difficult to prove a negative, we have, I think, every reason to believe that the granulation and crystallization of iron under vibration and shock is a myth."

Unquestionably the notion of a mysterious change produced by vibration in the quality of iron has worked double harm in stamp-mill practice. On the one hand, it has been the convenient excuse of manufacturers, who declare the evidences of bad workmanship shown in fractures to be the result of subtle changes thus produced in originally sound pieces of good metal. On the other hand, mill engineers, believing that the inevitable vibration would break anyhow, in the course of a few months, the jarring parts of their mills, have given too little attention to the distribution of stresses and shocks by which such breakages might be greatly delayed or wholly prevented. If they would lay aside their preconceived notions, and, disregarding even the opinion of the mill blacksmith, study the mechanical reasons for the liability of a stamp stem to break just over the head or just under the tappet, I think they would find more significance in the way tappet and head are attached to the stem (so as to subject it to heavy side shocks at points where it is not made stronger than elsewhere) than in any amount of molecular speculation.

Chemical Theories About Formation of Nuggets.

By Arthur Lakes, in the Mining Industry and Tradesman.

In opposition to the mechanical theory of the origin of nuggets it has been urged that nuggets are often found very far away from any parent vein or reef. Their small size offering little surface for the pressure of water, combined with their great weight, would hardly allow water to carry them to such a distance, and in favor of the chemical theory. Gold in placers is sometimes found in iron pyrites, assuming the form of rootlets and replacing coaly matter, implying chemical action and solution, and that gold existed in ordinary waters and deposited with pyrite. Gold, it is maintained, is contained in mineral waters permeating rocks and placers, influencing the precipitation of gold, which concretes around certain substances congenial to it, such as other loose grains of gold, cubes of pyrite, etc.

Gold in solution has this tendency, for chloride of gold was decomposed by a piece of cork falling accidentally into the solution, and was precipitated around a small piece of metallic gold that happened to be present, greatly increasing its size. Similarly it has been found to concrete around a cube of pyrites. Gold crystals sometimes contain iron ore or iron pyrites as a "nucleus." From this it appears that organic matter will decompose a solution of gold and precipitate it around some nucleus offered to it.

As to the fact that placer gold is generally purer than vein gold, this, too, is in favor of the chemical theory, as it is found that gold may be greatly purified of its alloy by dissolving and reprecipitating it.

Nuggets may be formed and particles of gold may increase in size, through deposit of gold from waters percolating through the placer. And as at the time of volcanic eruptions, such as were prevalent at the time of the "placer" formation, as shown by the lava capping of the deep placers of California, these waters were both hot alkaline and saline, and therefore especially favorable to carrying gold in solution. Gold exists in some saline waters and has been detected in sea water, in the latter case probably derived from the rocks. Gold, too, was found in solution in the water of a mine in New Zealand.

Again, the pebbles of conglomerates are at times found cemented with iron ore containing gold, implying solution, and that the gold salt was in the same solution that deposited the pyrites. Gold has a great affinity for silver or quartz. Gold probably came into the gold vein in a solution of quartz or silver, the latter derived from the elements composing the adjacent rock, such as mica, hornblende and feldspar. Gold probably exists in minute form in these little minerals.

All native sulphides, such as copper and iron pyrites, are liable to contain both silver and gold. In the decomposition of a vein charged with such metals, silver may be oxidized away in solution, while the gold will be carried off in a very minute state. Gold being alloyed with silver, and silver with gold, shows that at the time of decomposition the separation was incomplete.

In illustration of some of these chemical changes going on in placers, is the occurrence of gold in the deep lava-capped placers of California. These placers are gravel drifts of ancient river beds, covered up by lava-flows 100 to 200 feet thick. The placers are worked by tunnels driven beneath the lava. Waters percolating through these lava-flows and reaching the gravels below are charged with alkali from the alkaline minerals composing the lava. These alkaline waters are also charged with silver from other elements of the lava. Hence the driftwood of these ancient river-beds has been silicified by these silicifying waters. The gravels are also cemented by silica. These waters contained iron also, and deposited iron pyrites around the fossil wood. The gold may have been in solution in iron sulphate, or else along with the iron in alkaline sulphide.

While the wood decayed it was partially replaced by quartz and partly by iron pyrites, the latter produced by deoxidation of iron sulphate by the woody organic matter. In this pyrite gold is found, sometimes in rounded grains and sometimes in minute crystals and threads, the latter just as in the pyrite of the decomposed quartz vein. This gold was deposited from a solution of iron at the moment of the reduction of the latter to a sulphide. Speaking of nuggets, one authority says that, "although gold exists in the iron pyrites of the unchanged vein only in minute, even microscopic, crystals and threads, yet in the changed oxidized upper portion of the vein it exists in quite visible particles, and sometimes, but rarely, in large nuggets. This shows that sulphate of iron is the natural solvent of gold. These larger grains and nuggets result in the running together or coalescing of all the minute particles contained in a mass of iron pyrites into a mass of gold. By water the sulphide or iron pyrites is oxidized into sulphate and the gold redissolved. From this solution it crystallizes into one mass as the solution concentrates. In the case of large nuggets the gold is probably in some way deposited

constantly in the same place from a similar solution bringing gold for a long time."

In conclusion, we may add that there appears to be a good deal to say in favor of both sides, and it seems probable that while a large amount of the gold, especially the grains and smaller nuggets may be in the placer according to the mechanical theory as water-worn, water-born pebbles, yet in the case of the larger nuggets, the size of them, and their remarkably pitted exterior, would suggest either some chemical action having taken place in the placer itself, or else in the pyrites and gold of the vein before the nugget was transported there. The matter is still an open question.

Origin of Gold Nuggets.

I notice an interesting article on the "Origin of Gold Nuggets," by Arthur Lakes, in the *Industry* of April 5th, 1894. In connection with the different theories advanced, it might interest some to know the results of my personal experience since January, 1850, in California, Idaho, Montana and other places.

In the first place I have come to the conclusion that by far the greatest portion of placer gold is derived from the disintegration of quartz veins, but by no means all of it. In support of the quartz theory and the formation of nuggets from quartz boulders, rich in gold, I will give you an example or two.

In 1858 to 1860 I worked in Myrtle creek, Del Norte county, California. By far the greatest portion of the gold was of the coarse order, and nearly free from quartz. On working up the creek the gold suddenly stopped. We continued on for some distance but found it worse. We then tried the sides and found the gold golog under a heavy slide, and no longer smooth. It was rough and scraggly, showing that it had not been subject to so much attrition as that in the creek bed. A large quartz vein carrying iron and copper would, if it continued, cross the creek at this point. Below this vein, during heavy rains, we would sluice off the surface and pick up the nuggets. One we found weighed \$28, at \$17 per ounce. I suspected that it was not all gold, though quite smooth on the outside. On laying it on the anvil and striking it lightly it broke into numerous pieces. The fracture faces were all black as ink, but on examination showed fine gold particles and iron about equally divided. On grinding a small piece, it showed no indications of coarse gold, the particles being as fine as flour.

A large nugget of apparently solid gold weighing over nine ounces, on being cut in two, revealed one ounce of black sand without a particle of fine gold, showing that it had all become welded together by some process. On Clear Water, in Idaho, a piece of gold was picked up in the tail race showing a little quartz on one side. I broke it in two, and it showed exactly the same fine gold as the Del Norte piece, only the gangue was quartz. So much for that theory.

Now as to the other, or one way that nuggets are formed, or rather placed in placers.

In 1851 a party of us went to Auburn, Placer county, Cal., camping on Spanish Flat. We sank a hole at the lower end of the flat to bedrock, obtaining about ten cents to the pan in fine gold in about a foot of fine gravel, under three or four feet of clay. This was not a good ravine, seeing there was very little water, so we went to another ravine close by where there was more water. In a few days after we left, gold was found in the grass roots in large pieces, some as high as \$3000, and the most of the ground paid \$1500 to the wagon load. No gold could be found more than a foot deep. The heaviest pieces were found about the center of the flat, growing less in number and size toward the edges and running diagonally across the flat. On investigation it was evident to me that that gold fell in a shower on that particular place. Also that the pieces had cooled sufficiently to solidify before they struck. All had about the same shape, concave on one side, convex on the other. When I advanced this theory I was laughed at a good deal, but not one of the merry ones could explain how that gold got there otherwise. I would here mention that no trace of quartz was ever seen in any piece to my knowledge. If gold can fall as a meteor in one place, why not smaller ones in other places? The same state of affairs took place at Ballarat, Australia, the largest pieces lying many feet above bedrock. A year or two ago I noticed in the *MINING AND SCIENTIFIC PRESS*, San Francisco, that a meteor was found in Shasta county, I believe, rich in gold. Now, why should people look for solution and precipitation theories, when investigation would soon give them evidence abundant to account for the presence of nuggets in a natural manner?—C. J. Barclay, in Mining Industry and Tradesman.

AMONG recent inventions is an opera-glass which can instantly be converted into a photographic camera.

The Burial of the Living.

From evidence that it seems difficult to dispute, it appears that, in the Celestial Empire, old, incurably diseased and hopelessly depraved persons are frequently burned alive in order to rid the community of the burden and responsibility of their care-taking. This arrangement is the result of a mutual understanding, the victims assenting to and sometimes assisting in the preliminary ceremonies. The usage seems to have been recognized by the highest authorities, and the burials have certainly been conducted with the sanction of the ruling powers. Great preparations are made and there is much ado, and sometimes a show of grief, but a great deal of the latter is evidently perfunctory, as there is an all-around feeling of satisfaction on the part of the spectators and more or less complacency on the mind of the victim, who is comforted by the assurance that he is fulfilling a tradition and will earn the respect of his ancestors and gone-befores. This custom is scarcely more strange and barbarous than the Japanese practice of compelling a man for certain crimes or calamities to commit suicide. It would, at least, have its compensations in that the criminal could be made to take himself off, and thus leave no unpleasant reflections upon the mind of hangman or executioner.

THE limestone monument bearing the title used as a headline is located in Decatur county, Ind. The center of the population in the United States, as located by the census of 1890, is in the above-named county, 20 miles east of Columbus, one of the cities of Hoosierdom. This is the second time in the history of our country that the center of population has been indicated by marking it with a monument. The first was the spot located by the census of 1810. The "monument," which may still be seen, is simply a flat stone embedded in the soil 40 miles northwest of Washington, bearing these three words, "Center of Population."—St. Louis Republican.

IT may interest those who have read pension speeches to know that there are about 4000 persons living in foreign countries who receive checks from Washington quarterly in payment of pensions. There are 2000 in Canada, who receive \$345,000 a year; 600 in Germany, receiving \$98,000 a year, and 750 in Great Britain whose checks aggregate \$126,990 a year. One man in the Fiji Islands draws \$24 every three months, and four times a year checks are sent to men who are living in Africa.

A RATHER STARTLING INDUSTRIAL DEVELOPMENT is reported from Victoria, Australia, where women have been substituted for men at no fewer than 200 railway stations. The result has been a saving of \$150,000 per year in salaries. The average wage paid to a station mistress is \$100 per year, whereas "the objectionable male" used to receive \$750. But, as the *Sydney Telegraph* asks: "How is the Victorian woman going to support a husband and family on \$100 a year?"

A GERMAN authority is responsible for the statement that worms eat wood only to get the starch. Hence he advises that trees for telegraphic poles be girdled in the spring. The tree in its growth will then consume the starch in leaf formation, and when it dies in the autumn the wood will be starch-free, and hence will offer no attraction to the worms.

THE largest aluminum manufactory in France, producing 200 kilograms a day, is located near Grenoble. The Société Electrometallurgique Française has in course of construction at La Praz, in the adjoining department of the Savoie, a factory which will produce 1000 kilograms a day, and it is believed that its capacity will be increased to 10,000 kilograms.

PAUL HUMY of Chicago is the inventor of a novel form of armor plate, which will soon be given a trial by the Government. Humy's plan is to put the edge of the plate instead of the surface to the projectile of the enemy. The plate is to be composed of two-inch steel plates set on edge and bolted together.

THERE are fifty-three cities in Brazil which have a population of 5000 and upward, thirty-one which have a population of over 10,000, fourteen of over 20,000, seven of over 40,000. Para has about 60,000, Sao Paulo 70,000, Pernambuco 150,000, Bahia 180,000 and Rio de Janeiro 407,000.

SCIENTIFIC MEN have demonstrated that a speed of 200 miles an hour can never be attained by anything that moves on wheels.

AN alloy that adhered so firmly to glass that it may be used to solder pieces together is made by a French chemist.

The Blue Lakes Canal.

So closely connected are water enterprises with mining operations that reference to storage and distributing reservoirs is always interesting. Herewith are presented illustrations of some of the works of the Blue Lakes Water Com-

pany, which furnishes Amador county with a water system both cheap and efficient. In the high Sierras are situated the storage reservoirs, some of them at an altitude of 9000 feet, filled by melting snow, and carried at a daily delivery of nearly 50,000,000 gallons by pipes and flumes 40 miles down to the head of the Amador canal, which is 42 miles long, terminating near Sutter Creek. The canal's capacity is 3000
